ACKNOWLEDGEMENT

First and foremost, praises and thanks to God for His blessings, which I knew I could trust in throughout my research. I would like to express my sincere gratitude to my research supervisors, Prof. Dr. Angelika May and Prof. Dr. Jörg Prokop of the Carl von Ossietzky University of Oldenburg, for their continuous support of my Ph.D study and research, and for providing guidance throughout this thesis. I am especially grateful for the chance to write my Ph.D. in Munich while working part-time and founding a company. Besides my advisors, I would like to thank Prof. Dr. Armin Varmaz of the University of Bremen for his support with many methodological questions. I also extend my thanks to the members of the Center of Lebenslanges Lernen at the University of Oldenburg, where I worked as a mentor during my Ph.D. studies.

I am grateful to my parents, grandparents, sister, and brother for their love, their care for education, and the way they prepared me for the future. I am very thankful to my best friend Dr. Martin Zeckra, who shared every struggling and happy moment of my Ph.D., for his everlasting support. A special thanks goes to Dr. Carmen Preißinger, who provided fantastic support in the last months of my Ph.D. Also, I would like to express my thanks to my good friends Jana and Hanna, who supported me throughout every moment of my Ph.D; I am very happy to know them in my life. A special thanks goes the Evangelische Gemeinde Bogenhausen for the support of all the members of this Christian community. Last but not least, I thank my good friends in the "Jumping Fitness Group" at the Movement Fitnessstudio in Munich for the great fun we had doing sports together while I worked on my Ph.D.

ABSTRACT

The thesis is based on current research and definition attempts for alternative investment classes and is focused on their general and statistical properties. We analyze 39 time-series. The analysis is done for European banks.

Four research questions are answered. The first question is whether there is one comprehensive GARCH model describing all the 39 datasets. Secondly, it is investigated whether it is possible to find this model using a heuristic approach. Thirdly, the diversification effects on a traditional portfolio are discussed. Finally, it is examined whether the comprehensive GARCH model is applicable to portfolios with alternative investments.

The main result is that an exponential GARCH(1,2) model with a general error distribution matches 18 of the 39 datasets and nearly all portfolios. The model was detected by a heuristic approach. The risk of a traditional portfolio is reduced in most cases by adding alternative investment classes.

ZUSAMMENFASSUNG

Die Arbeit fokussiert auf die statistischen und qualitativen Eigenschaften von alternativen Investments. Wir analysieren dafür 39 Zeitreihen. Die Analyse erfolgt für europäische Banken auf Basis des aktuellen Forschungsstands.

Ausgangsfrage ist, ob ein umfassendes GARCH Modell alle 39 Datensätze beschreiben kann und ob das Auffinden dieses Modells mittels eines heuristischen Ansatzes möglich ist. Dann werden die Diversifikationseffekte auf ein traditionelles Portfolio untersucht. Letztlich wird geprüft, ob das umfassende GARCH Modell auch auf Portfolios mit alternativen Assetklassen anwendbar ist.

Ein Ergebnis dieser Arbeit ist, dass ein exponentielles GARCH(1,2) Modell mit General Error Distribution 18 der 39 Datensätze und nahezu alle Portfolios beschreiben kann. Dieses Modell konnte über einen heuristischen Ansatz gefunden werden. Das Risiko eines traditionellen Portfolios wird in den meisten Fällen durch die Beimischung von alternativen Assetklassen gesenkt.

1. Introduction

By the beginning of the twenty-first century, the value of assets managed as alternative investments had increased rapidly. Due to the magnitude of the capital involved in this sector, as well as the impact of those investments on the functioning of the international financial market, the subject continues to attract more attention.[1] Alternative investments are now considered an indispensable component of capital investment, especially for institutional investors.[2] This is not only because of their growing impact on the financial market, but also their potential to diversify portfolios and increase possible returns.

Thus, alternative investment has become an intensively studied field of research. Despite some general approaches that give an overview of alternative investments,[3] most quantitative and qualitative studies deal with their properties in terms of volatility modeling, impact on portfolio risk and return, and regulatory requirements.

However, the majority of these studies on alternative investments only cover one of the above-mentioned topics and examine, at most, a small selection of alternative investment datasets. What is missing, also due to the rapid development of the cryptocurrency market, is a broad overview, which allows for a comparison in terms of definitions, modeling and impact on portfolios. Besides that, the authors of many studies often consider different datasets, define alternative investments in different ways and expect different investor perspectives, making a comparison between the single results of the studies nearly impossible. Especially for institutional investors, this represents an unsatisfactory scientific basis. As this topic becomes more salient for institutional investors, particularly due to the regulatory requirements, it is clear that not only a quantitative overview is missing, but also a study with a dataset that is consistent, broad, and oriented towards banks as investors.

The research gap becomes more noticeable when considering the following examples: In terms of portfolios, Jaggi et al. in 2011 provide a methodology to combine long traditional asset classes with an active component. In doing so, the authors introduce traditional and alternative indices. Alternative indices for them are represented by different hedge fund

[3] See, for example, Dorsey 2007, Anson 2006, Mostowfi et al. 2013, Sokołowska 2016.

indices that stand for the "active component" of the portfolio.[4] However, this is different to the definitions provided by Sa-Aadu et al. in 2010, who investigated impacts on portfolios with corporate bonds, small cap stocks, commodities and precious metals, international stocks, and real estate.[5] Moreover, another differing portfolio approach is provided by Cumming, Schweizer, and Haß in 2014, who investigated a strategic asset allocation that can incorporate the special characteristics of alternative investments.[6] Several other studies deal with volatility modeling of a variety of different alternative investments returns with GARCH: for example, Ekong and Onye in 2017, who investigated six sets of symmetric and asymmetric GARCH-family models for Nigerian stock returns;[7] Kawaguchi, Sa-Aadu and Shilling in 2017, who examined the volatility implications of equity REIT stock return;[8] or Fakhfekh and Jeribi in 2020, who investigated sixteen of the most popular cryptocurrencies using five GARCH models with different error distributions.[9] In terms of regulatory requirements, several studies also exist. For example, Cumming et al. in 2012 investigated whether financial regulation can impact performance persistence in the context of the hedge fund industry,[10] while Cumming and Zambelli in 2013 investigated the impact of excessive regulation on private equity returns and firms' performance.[11]

While this weakness in the literature was only touched on by this short literature overview, it becomes even clearer in the literature chapter of this thesis.

There is no broadly agreed upon way to research the topic of alternative investments. Our thesis closes the gap and, hence, represents the consolidation of the topic's varying definitions, the concept of return modeling and the impact of alternative investments on portfolio risk into one comprehensive overview. Against the background of the regulatory requirements, the comparison regarding these topics provides the most benefits for institutional investors.

To conduct for these regulatory requirements and to provide a broad but manageable and usable overview on which further studies can conduct on, three assumptions for the further research are made. First, we conduct our analysis from the perspective of a

European bank. This allows us to concentrate on only one regulatory regime, namely Basel IV.[12] Second, the thesis takes hence the perspective of risk rather than return as banks are obliged to provide information concerning their risk exposure to the regulatory regime. Third, where it was possible only European data are used. As one of the weaknesses of the above addressed studies was that all the results were not comparable, one goal of the thesis is to provide homogenous datasets which makes the different results comparable. The use of European data only facilitates the data structure in terms of currency and missing data.

The creation of such a comparison basis is also interesting regarding the risk-oriented value management of the banks. Internal models were strongly promoted by the supervisory authorities until the mid-2000s. Since the financial crisis the regulators have turned away from this. The regulations have continued to increase, and they are much more restrictive, e.g., when it comes to quantifying capital or liquidity requirements with internal risk models used by the institution. However, banks still benefit from internal models because they use them for internal risk management and bank control processes as well as value-based management.[13] With a basis of comparison the internal model finding process can be simplified. Also, the investor is interested in risk reduction in order to keep the provision and, thus, the costs of equity capital as low as possible. The correct choice of asset classes and investments requires extensive research to determine the effects of these investments on regulatory requirements and then to incorporate these into the decision process of purchasing them. A comparison between different assets thus facilitates this research and enables a faster choice between them.

Against this background, four main research questions arise to ensure the research gap is closed precisely. First, we investigate whether it is possible to describe a dataset comprising 37 univariate alternative and two univariate traditional investment return time series using one comprehensive GARCH model. Second, we examine whether this GARCH model can be found using a heuristic procedure. Third, we explore the extent of any diversification effects alternative investments classes[14] have on traditional investment portfolios. Finally, we examine whether the model resulting from the first and second

[12] Cf. Basel Committee on Banking Supervision 2019.
[13] Cf. Romeike and Trummer 2018.
[14] The difference between the definitions of the terms ‘alternative investment’, ‘alternative asset class’ and ‘alternative asset category’ and how they are used in this thesis is explained in chapter 2.

research question is also applicable to portfolios with traditional and alternative investments.

We examine the first research question because we want to find out whether the properties of alternative and traditional time series are comparable in terms of volatility and volatility modeling. For this investigation, we analyze dataset made up of 39 European and American (where European data were not possible) time series over a five-year horizon. To ensure a consistent and homogenous dataset, which is necessary for answering the research question correctly, we conduct the data collection and the further data editing process very precisely and apply appropriate approximation techniques.

Univariate GARCH models are chosen for three reasons. First, as single alternative investments financial return time series are compared to each other the thesis concentrates on univariate models. Second, other model alternatives were also investigated, namely ARMA models, which provided no satisfying results.[15] Lastly, in the literature other authors[16] had also success by using univariate GARCH models for modeling financial log return time series.

The second research question allows us to provide banks a mechanism that makes it easier for them to find models for any time series within an investment portfolio or, indeed, the entire portfolio itself. Very complex modeling procedures can then be reconsidered and complemented or replaced by heuristic procedures. As such, we test different GARCH models on every single dataset, assuming that one of these models best describes the datasets and the portfolios. The assumption that one comprehensive GARCH model, describing all of our time series, exists is based on so-called stylized facts about financial time series, meaning that they have common statistical properties.

For answering research question three we concentrate on the downside risk measured with the expected shortfall, which is in line with the regulatory requirements in Basel IV. As the main focus in the thesis is due the perspective of a European Bank on the risk rather than the return, no further research is done on the risk performance measurement or portfolio optimization.[17]

[15] See footnote 251.
[16] See, for example, Ekong and Onye 2017, Chu et al. 2017, Troster et al. 2018.
[17] For further research on that topic in terms of alternative investments see, for example, Glas and Poddig 2018, Cao et. al 2017, Yu et al. 2019.

The fourth question is examined to adequately conclude the basis of comparison. Institutional investors can easily check for different impacts on their portfolios with traditional investments. We investigate this by creating portfolios with traditional investments, namely equities and bonds, and alternative investments. To do so, we group our time-series dataset into 14 subgroups, with the first subgroup representing a reference portfolio made up of bonds and equities.

This thesis is structured as follows:

Chapter 2 outlines and defines approaches found in the literature and regulatory requirements, as well as the documentation provided by the German cross-asset and cross-product advocacy association for the alternative investments industry, Bundesverband Alternativer Investments. Additionally, in this chapter we clarify our understanding of alternative investments to provide a unique use of the terminology throughout this thesis.

Chapter 3 is devoted to our dataset and methodology. To meet the requirement of a broad overview, we present our dataset, which contains financial time series for the following asset classes: commodity futures, cryptocurrencies, private equity, bonds, and several European stock indices representing different alternative investment categories. Traditional investments are represented by the German Rex and the STOXX Europe Total Market index. For backtesting purposes, we split this dataset into in-sample and out-of-sample parts. Here, we also provide knowledge about the data collection process and descriptive statistical measures. Furthermore, we present stylized facts for financial time series, representing the basis for our GARCH model assumptions.

The methodology is as follows: We test different GARCH models on every single dataset, assuming that one of these models best describes the datasets and the portfolios. To this end, we combine five different GARCH models (Standard GARCH, Integrated GARCH, Exponential GARCH, GJR-GARCH and CS-GARCH) with three different distributions (normal, Student's t- and general error distribution) and a varying conditional mean model. The model evaluation is conducted in three steps, performed separately for each of the models per time series: firstly, we consider the significance and persistence of the model parameter of each model; secondly, we investigate the forecasting performance for each of the remaining models using McNeil and Frey's[18] expected shortfall backtest;

[18] Cf. McNeil and Frey 2000.

finally, if the backtest is successful, we choose the remaining models and evaluate them using the Akaike information criterion. To answer the third research question, we create portfolios of traditional and alternative assets. As a result, we create one traditional and 52 mixed portfolios, all of which are treated as new univariate time series. Since we analyze sub-indices of the STOXX Europe Total Market index, we use a regression-based approach allowing us to count the error terms as new time series and build new portfolios out of them, which is why there are 32 additional portfolios. What we prove additionally, answering the fourth research question, is whether the comprehensive GARCH model for the univariate time series can also describe the portfolio volatility. This allows us to understand whether banks could even predict their portfolio time series with only one GARCH model. To complete our research in terms of law, we consider the newest Basel IV requirements as we implement the internal model approach and use these regulatory requirements as a basis for our calculations.

Chapter 4 concentrates on the theoretical background for all techniques introduced in chapter 3 and presents the empirical results of our calculations. Finally, chapter 5 provides a discussion of our results and final conclusions.

The main result of the thesis is that an EGARCH(1,2) with a general error distribution describes both the single time series and the portfolio time series. Finding this model was possible by implementing a heuristic procedure. With respect to cryptocurrencies and some individual exceptions, all portfolios showed reduced risk when adding alternative investments. The summary of the results represents the comprehensive overview.

2. Alternative and Traditional Investments

2.1. Definitions

This chapter is devoted to both finding unique definitions of alternative and traditional investments, asset classes, and categories and providing a literature overview of the most important and recent research fields concerning alternative investments. Since no single definition exists in either the literature or in regulatory requirements, we present several approaches found in the literature. For a correct and consistent use of terminology throughout the whole thesis, we determine a definition based on these presented approaches. We emphasize especially that we distinguish here between alternative investment assets, categories, and proxies, as not all alternative investments have a sufficient data basis for an empirical analysis.

There are several approaches to defining alternative investments. Dorsey in 2007 simply counted hedge funds, funds, private equity, real estate, currencies, commodities, timber, and oil and gas as alternative investments. He pointed out that alternative investments not only have a range of types (like private equity, real estate and commodities) and a range of strategies (like leverage buyouts, mezzanine dept, and venture capital) but also an entire genus of factors (such as credit spreads, volatility, and liquidity).[19]

Anson et al., however, based their arguments on asset classes in 2011. They remark common stocks, bonds, cash equivalents and real estate as the four major asset classes in developed countries. They stated that investments may be summarized as an asset class if they meet the following key characteristics: major economic factors influence the value of the asset class and correlate highly with returns of each member included in the asset class; the investments have similar risk and return characteristics; and the investments have a common legal or regulatory structure. This led them to the assumption that the correlation between two different classes would be low and, hence, reduce risk. Further, they pointed out that these asset classes can be extended to create other asset classes, e.g., common stocks and bonds are commonly further partitioned into more asset classes. They categorised all asset classes referring to bonds and equities as traditional asset classes and

[19] Cf. Dorsey 2007, p. 3f.

all others as alternative asset classes, including hedge funds, private equity, and commodities.[20]

Mostofwi et al. in 2013 defined alternative investments as a heterogeneous group of investment opportunities differing from traditional investments in terms of their risk and return characteristics, as well as certain other characteristics such as liquidity and market efficiency. They distinguish between alternative investment strategies (hedge funds and private equity) and real assets (commodities, real estate, and collectibles). In contrast, traditional investments only include, in their opinion, equities, bonds, and derivatives, as well as structured products with equities and bonds as their underlying.[21]

Baker and Filback stated in 2013 that alternative investments refer to asset classes that fall outside of traditional investments, such as stocks, bonds and cash. With reference to Yau et al.[22], they introduced the concepts of traditional and modern alternative investments. They count real estate, private equity and commodities as traditional alternative investments and managed futures, hedge funds and distressed securities as modern alternative investments.[23]

Sokolowska connected in 2016 to this point in a more recent study. With reference to Anson[24] and Kizer[25], she pointed out that literature does not clearly define whether alternative investments should be regarded as a separate category of assets or as a subcategory of assets already existing on the financial market.[26] Additionally, referring to Leitner et al.,[27] she specified the characteristic features of allocating given investments into a category of alternative investments, since no unified definition of alternative investments exists. These include the following: a higher return rate potential adjusted for the risk; low correlation with traditional instruments; investments are traded outside the traditional exchange-traded market on the OTC; transaction infrequency and, thus, lower liquidity; a long-term investment horizon; the application of diverse investment strategies, including a financial leverage, short-selling and derivatives; a focus on the

[20] Cf. Anson et al. 2011, p. 7ff.
[21] Cf. Mostowfi et al. 2013, p. 12f.
[22] Cf. Yau et al. 2007.
[23] Cf. Baker and Filbeck 2013, p. 3f.
[24] Cf. Anson 2006.
[25] Cf. Swedroe and Kizer 2008.
[26] Cf. Sokołowska 2016, p. 2.
[27] Cf. Leitner et al. 2007.

achievement of absolute return rates; exposure to fewer financial regulations and higher costs; and the limited availability of investments. To qualify an asset as an alternative investment, Sokolowska added that alternative investments generally have a higher investment risk compared to traditional financial investments, negative correlation between the return rates and the profitability of traditional investing. Furthermore, the investments require specialized knowledge, often non-financial. In her opinion, alternative investments focus on a wealthy investors target group and work within a market segment characterized by lower informational requirements and lower transparency levels.[28] In a brief overview, she summarized real estate, commodities, structured products (e.g., products linked to equity, exchange rates or interest rates), funds, and emotional investments (e.g., art, wine, automobile, collectibles) as alternative investments.[29]

There are also some legal definitions of alternative investments. For the Commission of the European Communities, alternative investments only include private equity funds and hedge funds, which they state in the Green Paper on enhancement of the EU framework for investment funds. They explain also that the alternative investment industry offers new diversification benefits for asset managers. In their opinion, alternative investment strategies are more complex and may involve higher risks for investors than mainstream UCITS.[30] The European Union Directive defines the term AIF (Alternative Investment Fund) as follows (Directive 2011/61/EU): "'AIFs' means collective investment undertakings, including investment compartments thereof, which: (i) raise capital from a number of investors, with a view to investing it in accordance with a defined investment policy for the benefit of those investors; and (ii) do not require authorization pursuant to Article 5 of Directive 2009/65/EC".[31] In contrast to the other authors, the European Parliament has a very limited view on alternative investments.

The Bundesverband Alternativer Investments (BAI) defines alternative investments as innovative investment strategies and concepts that serve to better diversify and optimize the portfolio's risk-return structure. They argue that the term is often associated with infrastructure or private equity. Their general definition is that alternative investments are

[28] Cf. Sokołowska 2016, p. 5f.
[29] Cf. Sokołowska 2016, p. 10.
[30] Cf. Comission of the European Parliament 2005, p. 9.
[31] European Parliament 2011, p. 16.

investments in non-traditional asset classes (other than shares and bonds) or the investment in these asset classes with the help of more complex, non-traditional strategies. In accordance with the different approaches found in literature, the BAI also understands the field of AI to be an extension of private debt, real estate, hedge funds or commodities, as well as many other specialties, such as aircraft or ship financing and crypto-assets. In line with Sokolowska, they assert that there is both an absence of a universally recognized definition and that alternative investments are often characterized by special features, like higher return rate potential and possibly lower liquidity and transparency. The BAI further distinguish between public markets, which are mainly liquid, and private markets, which are mainly illiquid. They split public markets into

- liquid alternatives (e.g. crypto assets),
- hedge funds, and
- commodities (e.g. coffee, soybeans),

and private markets into

- corporate (e.g. private equity or private debt),
- real estate,
- infrastructure (e.g. transportation, communication, energy),
- other real assets (e.g. aviation, shipping, agriculture and forestry), and
- specialties (e.g. regulatory finance).

Given this definition, nearly all of the above-described approaches are found in the wide definitional approach of the BAI.[32] As this thesis provides a broad overview of alternative investments, a definition that is too specific will not lead to a satisfying discussion basis. Although we analyze mainly European data, the definition used by the EU is not sufficient for our needs. For this reason, we use the broader definitional approaches utilized by both the BAI and Sokolowska as our discussion basis. Moreover, we use Anson et al.'s[33] definition of an asset class since the BAI does not provide one.

To summarize the results, we utilize the following definitions in this thesis: Alternative investments, in general, are investments in non-traditional asset classes characterized by special features like higher return rate potential and possibly lower liquidity and

[32] Cf. Bundesverband Alternative Investments e.V. 2020.
[33] Cf. Anson et al. 2011.

transparency.[34] Traditional asset classes in this thesis are represented by stocks and bonds. An asset class is represented by summarized investments which meet the following key characteristics, as stated by Anson: major economic factors influence the value of the asset class correlate highly with the returns of each member included in the asset class; the members included in the asset class have similar risk and return characteristics; they also have a common legal or regulatory structure.[35] We, hence, define the different investment possibilities like bonds, stocks, currencies, or futures as asset classes. To be precise, we designate alternative investment categories as the subgroups of the public and private market suggested by the BAI. To summarize, we name alternative investment asset categories as alternative investments in this thesis, with the following examples illustrating how this naming convention functions in subsequent chapters: commodities are termed alternative investment categories, commodity futures are alternative asset classes, and cocoa is termed an alternative investment.

From the empirical perspective of the thesis, we face a problem that has already been articulated by Sokolowska, namely that alternative investments are characterized by infrequent transactions and, thus, lower liquidity, which makes data collection more difficult. As we seek to analyze a comprehensive overview of the alternative investments as stated by the BAI and Sokolowska, we have been forced to look for proxies for some alternative investment classes, a decision in line with other authors.[36] In terms of our definitions for the thesis, we therefore have to be precise which terminology we use for our data. These proxies are represented by different stock indices, which are presented in detail in section 3.1. As long as we use stock-indices as proxies we, of course, do not analyze an alternative investment directly but assume the proxies to be directly linked to the real alternative investment. When we do so, we define this proxy as stocks linked to alternative investment categories.

2.2. Literature Overview

2.2.1. Alternative Investments in Portfolios

This chapter is devoted to the literature on alternative investments. In line with the scope of the thesis, we present studies of alternative investments dealing with the investigation of their risk behavior, impacts on portfolios, how they are modeled and forecast, and their behavior in terms regulation and law. Finally, we provide a short overview of other fields of research, such as liquidity aspects of alternative investments or using them as hedge instruments. This chapter illustrates the different approaches to alternative investments and highlights the research gap.

Various studies on the benefits of adding specific alternative investments to portfolios were carried out in the late 1990s and early 2000s, e.g., see Fung and Hsieh[37], Amin and Kat[38], and Agarwal and Naik[39] for Hedge Funds; Akey for commodities[40]; Black[41] for volatility; and Hung et al.[42] for real estate. Additionally, there was intense research about the role of hedge funds in traditional portfolios, e.g., by Amenc and Martinelli[43] in 2002 or Gueyié and Amvella[44] in 2006. Further investigations in the portfolio context where undertaken on the diversification effect of alternative investments on equity and bonds, e.g., see Hafner and Wallmeier's[45] or Hoevnaars et al.'s [46] studies. In contrast to that, Pézier and White's 2008 paper pointed out the relative merits of alternative assets in passive portfolios.[47]

Sa-Aadu et al. found that there are real economic benefits when investors extend their portfolio of assets to include alternative assets (corporate bonds, small cap stocks, commodities and precious metals, international stocks and real estate). In addition, they

[47] Cf. Pézier and White 2008.

pointed out that the attractiveness of an asset class in a portfolio context depends on the timeliness of the gains in portfolio performance.[48]

Jaggi et al. in 2011 provided a methodology to combine long-only traditional asset classes with an active component. In this regard, they introduced traditional indices, represented by bonds, credits, equities, real estate commodities and emerging markets, and alternative indices, represented by hedge fund indices, which stands in contrast to our definition of alternative investments. With exception to bonds, they introduced, for each traditional index, an appropriate hedge fund index representing the "active component" for the portfolio, e.g., they presented the S&P Commodity Index as the traditional index and the Commodity Hedge Fund Index as an alternative complement. They provided a substitution approach which looked at hedge funds in the context of the underlying markets in which they operate. Their conclusion was that the substitution approach leads to results similar to an optimization approach in which the hedge fund portfolio is optimized as a stand-alone investment class and then added to the traditional portfolio.[49]

In 2014, Cumming, Haß, and Schweizer investigated a strategic asset allocation that can incorporate the special characteristics of alternative investments. Therefore, they dealt with a variety of alternative investments, e.g., commodities, private equity, hedge funds, and real estate. Additionally, they applied a goal function to examine real investors' preferences. The authors highlighted the fact that return distributions of alternative investments have significantly higher moments that the standard deviation does not cover. As such, every standard method for portfolio optimization is likely inaccurate for alternative investments. Their further investigation was founded on the construction of strategic asset allocation, taking into account the special distribution properties of the alternative investments and the investor's objective. Their key result was that their approach outperforms the classic Markowitz mean-variance-approach and provides robust results.[50]

Jacobs et al. evaluated numerous diversification strategies as a remedy against the widespread costly investment mistakes of individual investors. Based on their results, they revealed that a broad range of simple heuristic allocation schemes offer similar

[48] Cf. Sa-Aadu et al. 2010.
[49] Cf. Jaggi et al. 2011.
[50] Cf. Cumming et al. 2014.

diversification gains, such as well-established or recently developed portfolio optimization approaches. The authors concentrated on eurozone individual investors and incorporated stocks, bonds and commodity futures in their analysis. They excluded real estate, hedge funds and private equity because other authors, such as Amin and Kat[51] in 2003, found their diversification potential in the multi-asset case to be limited. Secondly, they could not identify indices that met their selection criteria.[52]

Alexander et al. in 2016 investigated the diversification effects of volatility products and commodity futures. They found that long equity and bond portfolios diversified with volatility futures have not performed as well as those without diversification, or even those diversified with commodities.[53] In the same year, Jackwerth and Slavutskaya discovered that the inclusion of alternative assets in pension fund portfolios yielded positive effects. They did this by measuring the Manipulation Proof Performance Measure of pension fund portfolios without additional alternative assets, selling 10% in proportion to the portfolio and investing this 10% into alternative assets.[54]

In line with Pézier und White[55], Platanakis et al. in 2018 found harmful diversification effects for US Investors when adding five alternative investments (real estate, commodities, hedge funds, emerging markets and private equity) to equity and bonds portfolios. They used 19 portfolio models in conjunction with dummy variable regressions to investigate the harm. To do so, they formed eight portfolio types of mean-variance-analysis, eight of ad hoc model and three models maximizing a utility function with three levels of risk aversion, thereby connecting to the approach followed in Cumming et al.'s 2014 study. Their key finding was that harmful diversification is not primarily due to transaction costs or non-normality, but to estimation risk. This effect is larger for alternative assets during the credit crisis (real estate, private equity, and emerging markets) and stays for commodities and hedge funds even when the crisis is excluded.[56]

In recent years, extensive research has been carried out in the field of cryptocurrencies and their behavior in traditional and mixed portfolios. Brière et al. in 2015 analyzed Bitcoin with a diversified portfolio that included both traditional and alternative investments and found that Bitcoin offers significant diversification benefits.[57] Pinudom et al. in 2018, using a multivariate t-copula based on GARCH, investigated the effect of adding Bitcoin to a portfolio of the crude oil price index, the stock exchange of Thailand (SET) price index, the exchange rate between Thai and USD, and the Thai government bond compound with treasurer bill. They found that by adding more Bitcoin into the portfolio the return and risk of the asset increased.[58] Elizabeth and Kumar in 2018 analyzed the performance and interdependency of cryptocurrencies.[59] In the same year, Klein, Thu and Walther investigated whether Bitcoin behaves like gold in terms of volatility, correlation and portfolio performance. They concluded that Bitcoin behaves as the exact opposite of gold.[60]

Guesmi et al., using different multivariate GARCH specifications, investigated the proprieties of Bitcoin and examined the conditional cross effects and volatility spillover between Bitcoin and financial indicators. They found that VARMA(1,1)-DCC-GJR-GARCH is the best-fit model for modeling the joint dynamics of a variety of financial assets and that hedging strategies involving gold, oil, equities and Bitcoin reduce the portfolio's risk, as compared to the risk of the portfolio without the cryptocurrency.[61] Symitsi and Chalvatzis showed that there are significant diversification benefits to including Bitcoins in a portfolio of traditional and alternative assets which are not offset by its high volatility. Additionally, they found evidence that Bitcoin can even lead to significant reduction of the overall portfolio risk.[62]

2.2.2. Modeling Alternative Investments using GARCH

It is possible to utilize several approaches in GARCH modeling. This section discusses the theoretical studies first and then the empirical studies.

The Autoregressive Conditional Heteroskedasticity model was introduced by Engle[63] in 1982 and the extension to GARCH models by Bollerslev[64] in 1986. These theoretical approaches are further explained in section 4.4. Additional expansions were examined by Bollerslev[65], with the Student-t GARCH model, Nelson[66], with the EGARCH model, and Glosten et al.[67], with the GJRGARCH model. Other notable additions that were made in other directions included, e.g., the TGARCH model of Zakonian or the extensions of Bollerslev et al.[68], Bollerslev et al.[69] and Engle[70].

Further theoretical studies were provided by Hansen and Lunde. For example, in 2005 they investigated whether sophisticated volatility models beat the parsimonious model GARCH(1,1). To this end, they compared 330 ARCH-type models in terms of their ability to describe the one-day-ahead conditional variance for DM-$ exchange rate and IBM return data. They evaluated their results with six different loss functions (MSE, QLIKE, MAE, MSE, R^2LOG and MAE). For the DM-$ exchange rate, they found that the GARCH(1,1) model was superior to all others; however, in the analysis of IBM returns it was clearly outperformed.[71]

Several studies deal with different models of the GARCH-family applied to alternative investments. The following sections introduce the most important literature relevant to this thesis regarding several alternative investment classes and the use of various GARCH models. These sections aim to provide a broad overview of the different research fields regarding GARCH. Hence, we also present papers concerning GARCH-models that are not part of this thesis.

[69] Cf. Bollerslev et al.1994.
[70] Cf. Engle 2004.
[71] Cf. Hansen and Lunde 2005.

For commodities, Sun modeled equity return in 2017 using a hybrid ARIMA-GARCH Model. He investigated Dow Transportation, S&P 500 and VIC and provided a hybrid ARIMA-GARCH model describing the return data. For the model fitting procedure, he used the Akaike Information Criterion (AIC).[72]

In 2019, De la Torre-Torres et al. tested Markov-switching GARCH (MSGARCH) models for trading either oil or natural gas futures and found that the use of the MSGARCH with fixed time variance leads to best performance in the oil market. For natural gas they found no benefits of using their trading rule against a buy-and-hold strategy for three-month U.S. Treasury bills. The following year, De la Torre-Torres et al.[73] also investigated MSGARCH in the context of coffee, cocoa, and sugar futures. They found that Student-t MSGARCH models are appropriate for active trading in cocoa futures, while Gaussian MSGARCH models are appropriate for sugar futures. For coffee, the MSGARCH displayed no evidence.[74]

Paraschiv, Reese, and Skjelstad constructed a portfolio of commodity futures which mimics the Dow Jones Commodity Index and performed a stress-testing exercise in line with Basel IV in 2020. For the distribution of portfolio component returns, they modeled an asymmetric AR-GARCH model combined with Extreme Value Theory for extreme tails and employed multivariate copula functions to model time-varying joint dependence structure.[75]

In the same year Vartanian evaluated the contagion of volatility between the commodity prices and the main stock Index of Brazil (Ibovespa) through a multivariate GARCH model to verify the possibility of diversification.[76]

The more recent studies on alternative investments in terms of GARCH models deal mainly with cryptocurrencies. Especially in the context of our thesis, this topic is important since, to the best of our knowledge, no author before has proven whether a

[75] Cf. Paraschiv et al. 2020.
[76] Cf. Vartanian 2020.

GARCH model, which works for other alternative investments, also works for the research field of cryptocurrency.

In 2014, Glaser et al. used the ARCH and GARCH(1,1) approach for investigating user intentions when changing their domestic currency into a digital one. They found that users mainly use Bitcoins as an alternative investment vehicle.[77] In the same year, Gronwald used a jump-intensity GARCH model for analyzing Bitcoin data and found that this model clearly outperforms a GARCH(1,1).[78]

Dyhrberg investigated in 2016 how the return on Bitcoin behaves in terms of the variance of the assets when compared to the gold price and the dollar-euro exchange rate. For this, she introduced two models to investigate the similarities between Bitcoin, gold, and the dollar. Using the asymmetric GARCH model, she demonstrated that Bitcoin may be useful in risk management and ideal for risk averse investors in anticipation of negative shocks to the market.[79]

Bouoiyour and Selmi investigated in the same year EGARCH, Asymmetric Power ARCH, weighted GARCH and component GARCH models with multiple thresholds for Bitcoin data, answering the question whether there is a beginning of a mature crypto-market, or a calm period that precedes upheaval. For model evaluation, they used daily data and in-sample criteria such as the Akaike information criterion (AIC), the Bayesian information criterion (BIC) and the Hannan-Quinn information Criterion (HQC). They found that the Bitcoin market is far from mature.[80]

Katsiampa in 2017 pointed out that all the previous authors, excepting Bouoiyour and Selmi, who compared different models, left one question unanswered: namely, which model can better describe Bitcoin data? To answer this question, she investigated GARCH, EGARCH, TGARCH, Asymmetric Power ARCH, Component GARCH and Asymmetric Component GARCH models, finding that the ACGARCH model fits best. In line with Bouoiyour and Selmi, she used AIC, BIC and HCQ for model evaluation.[81]

[79] Cf. Dyhrberg 2016.
[80] Cf. Bouoiyour and Selmi 2016.
[81] Cf. Katsiampa 2017.

Chu et al. considered more than one cryptocurrency and investigated twelve GARCH models in 2017. These models had innovation process distributions that were taken to be one of the following: a normal distribution, skew normal distribution, Student's t-distribution, skew Student's t-distribution, skew generalized error distribution, normal inverse Gaussian distribution, generalized hyperbolic distribution, or Johnson's SU distribution. For evaluation purposes, they used AIC, BIC, Consistent AIC, corrected AIC, and HQN. They found that, with normal innovations, IGARCH(1,1) yields the smallest AIC for Bitcoin, Dash, Litecoin, MaidSafeCoin and Moncro, whereas GJRGARCH(1,1) and GARCH(1,1) yield the smallest AIC for Dogecoin and Ripple.[82]

Fakhfekh and Jeribi investigated in 2020 sixteen of the most popular cryptocurrencies using five GARCH models with different error distributions. They found that the majority of cryptocurrencies turn out to be effectively modulated via TGARCH with double exponential distribution.[83]

In contrast to the previous authors, there are several approaches used for testing further extensions to GARCH models in the cryptocurrency context. Caporale and Zekoh sought to find the best model set, explaining the volatility of the most popular cryptocurrencies (Bicoin, Etherum, Ripple, Litecoin) using a Markov-switching GARCH model whose parameter could change over time. They fitted more than 1000 GARCH models to the log returns of the exchange rates of these cryptocurrencies to estimate a one step-ahead prediction of value at risk and expected shortfall. In contrast to this thesis, the authors based their analysis on a rolling window basis. To evaluate their results, they used the backtesting results of value at risk and expected shortfall and a Model Confidence Set procedure for their loss functions.[84]

In 2018, Troster et al. performed a general GARCH and GAS analysis for modeling and forecasting Bitcoin returns and risk, and compared out-of-sample 1% value at risk forecasts under 45 different specifications using three backtesting procedures. They introduced EGARCH, APARCH, GJRGARCH, T-GARCH, CGARCH, NGARCH, and H-GARCH models with normal, Student-t, Skewed t-Student, Johnson's Reparametrized SU, and generalized error distribution. They found that GAS models with heavy-tailed

[82] Cf. Chu et al. 2017.
[83] Cf. Fakhfekh and Jeribi 2020.
[84] Cf. Caporale and Zekokh 2019.

distributions provide the best out-of-sample forecast and goodness-of-fit properties to Bitcoin returns and risk modeling.[85]

Regarding REITS, Devaney investigated in 2001 the return generating process of real estate investments trusts (REIT) by employing the generalized autoregressive conditionally heteroskedastic in the mean (GARCH-M) methodology.[86] Sing, Tsai, and Chen used in 2007 a Markov-switching autoregressive conditional heteroskedasticity (MS-GARCH) model to filter out high volatility states from low and medium volatility states and found that volatility persistence increases the returns of EREITS (equity real estate investment trust).[87] Zhou and Kang compared in 2011 several well-known models to forecast REIT volatility: simple symmetric and asymmetric GARCH models, considered as GARCH-class; post-GARCH models, considered as stochastic volatility (SCV); Fractionally Integrated GARCH (FIGARCH) models; Fractionally Integrated Exponentially GARCH (FIEGARCH) models; and Fractionally Integrated ARMA models. They used daily REITS total return indices and measured the forecast accuracy with root mean squared error and mean absolute error, comparing them over six forecast horizons. They found that the long-memory models (ARFIMA & FIGARCH) outperformed the short memory models (GARCH and SV).[88] Kawaguchi, Sa-Aadu, and Shilling examined in 2017 the volatility implications of equity REIT stock returns and found a negative leverage effect in the pre- and post-Greenspan era using different GARCH models.[89]

Another field of research considers emerging markets, which are not going to be analyzed in this thesis but present relevant results we can refer to in our empirical work. 2017 Ekong and Onye investigated six sets of symmetric and asymmetric GARCH-family models of stock return volatility in Nigeria. In addition, and in contrast to Zhou and Kang, they took three different error distributions into consideration (normal, Student's t- and generalized error distribution). They evaluated their results, like Zhou and Kang, with the root mean squared error and Thiel's Inequality coefficient. GARCH(1,1) and augmented

[85] Cf. Troster et al. 2018.

[88] Cf. Zhou and Kang 2011.
[89] Cf. Kawaguchi et al. 2017.

EGARCH(1,1) in generalized error distribution were found to provide the best forecasting capability.[90]

2.2.3. Alternative Investment and Risk

Pedersen et al. investigated in 2014 solutions to measure mark-to-market risk in alternative and illiquid investments. They categorized alternative investments as private equity, real assets (e.g., real estate, farmland, infrastructure, and hedge funds), and exotic beta strategies. Their main result was that alternative investments are exposed to many of the same risk factors that drive stock and bond returns.[91]

Stavroyiannis investigated in 2017 the value at risk and expected shortfall properties for the major digital currencies: Bitcoin, Ethereum, Litecoin, and Ripple. He found that these cryptocurrencies are subject to higher risk, higher sufficient buffer, and risk capital.[92] Moreover, Borri estimated in 2019 the conditional tail-risk using CoVaR in the markets for Bitcoin, Ether, Ripple, and Litecoin and found that these cryptocurrencies are highly exposed to tail-risk within cryptomarkets, although they are not exposed to tail-risk for other global assets, like the U.S. equity market or gold.[93]

2.2.4. Alternative Investments and Law

In 2012, Cumming et al. investigated whether financial regulation can impact performance persistence in the context of the hedge fund industry in 48 countries from 1994-2008. They showed that minimum capital restrictions, as well as restrictions on the location of key service providers and distribution channels, decrease the likelihood of persistence.[94] Cumming and Zambelli investigated in 2013 the impact of excessive regulation on private equity returns and firm performance.[95] In 2017, Tokarevich and Jüttner discussed whether a structuring of alternative investments leads to a reduction of regulatory requirements when considering the Look-Through-Approach of Solvency II.[96]

[90] Cf. Ekong and Onye 2017.
[91] Cf. Pedersen et al. 2014.
[92] Cf. Stavroyiannis 2017.
[93] Cf. Borri 2019.
[94] Cf. Cumming et al. 2012.
[95] Cf. Cumming and Zambelli 2013.
[96] Cf. Tokarevich and Jüttner 2017.

Cumming et al. analyzed in 2019 the Security and Exchange Commission's initial statements and subsequent pronouncements on ICOs to illustrate the potential problems with applying an older legal framework to an ever-evolving ecosystem. Additionally, they discussed the importance of regulation of the crypto asset class and internal collaboration between government agencies and developers in the establishment of an ecosystem that integrates investor protection and investments.[97]

2.2.5. Further Fields of Research

Several further fields of research examine single alternative investments. For the sake of completeness, we present some of these research fields and studies. For example, some studies on gold have analyzed whether it could be used as hedge instrument: In this regard, Baur and McDermott investigated in 2010 whether gold is a safe haven and examined the role of gold in the global financial system. They found that it was a hedge and a safe haven for major European stock markets and the US but not for Australia, Canada, Japan, and large emerging markets such as the BRIC countries.[98] In 2018, Shakil et al. investigated a comparable research question, namely whether gold is a hedge or safe haven. For their analysis, they used an autoregressive distributed lag model and found that gold is useful as a portfolio hedge and as a hedge against inflation.[99]

Some authors have dealt with direct alternative investments like wine and art. Campbell investigated art as financial investment,[100] whereas Aytac et al. analyzed wine as a financial asset in the diversification of French investors' portfolios. The latter concluded that French investors, based on their findings, should invest in wine since they recorded high portfolio performance.[101]

Other empirical studies have examined alternative investments regarding other topics than those examined in this thesis. For example, Jurek and Stafford analyzed the cost of capital for alternative investments and found that the high excess returns to hedge funds and put-writing are consistent with an equilibrium in which a small subset of investors

[97] Cf. Cumming et al. 2019.
[98] Cf. Baur and McDermott 2010.
[99] Cf. Shakil et al. 2018.
[100] Cf. Campbell 2007.
[101] Cf. Aytaç et al. 2016.

specialize in bearing downside market risks.[102] Kräussl et al. demonstrated that pension funds' allocations to alternative assets have increased rapidly during the last decade, consistent with the search for yield in a low-interest rate world.[103] Furthermore, Peterson explained why the adoption of a time-weighted rate of return methodology as a performance measure for illiquid, private investments is misguided.[104]

This brief description was only intended to illustrate that there are many more research fields concerning alternative investments. We do not go into further detail here, as this would not contribute to the overall result of the work.

What becomes clear throughout the chapter is that there is no broadly agreed-upon way to research the topic of alternative investments that provides a comprehensive basis for comparison. The following chapters show how we close this research gap for banks as an investor.

[102] Cf. Jurek and Stafford 2015.
[103] Cf. Kräussl et al. 2017.
[104] Cf. Peterson 2016.

3. Data and Methodology

3.1. Data

3.1.1. Choice of Data

To provide a precise and broad overview of alternative investment classes, we analyze the following alternative investment categories: traditional investments, commodities, cryptocurrencies, private equity, emotional investments, energy, infrastructure, various datasets here titled with "other", and real estate, more specifically, REITS. As Sokolowska stated, alternative investments are characterized by infrequent transactions and, thus, lower liquidity, which makes data collection more difficult. In line with other authors,[105] we face this problem by using proxies, which are explained in more detail below. These proxies cover the following asset classes: stocks, bonds, cryptocurrency, futures, private equity and stocks linked to alternative asset categories. One exception is REITS, which is why it is found at the end of the above-mentioned enumeration. Although here we take stock index proxies for REITS, which is why we speak strictly of stocks linked to alternative asset categories, one might argue that this is an own asset class since these indices exactly represent what REITS are, namely investing in companies that take money for the purchase of real estate. But as we have more than one dataset in this category, we speak strictly of stocks linked to alternative asset categories. The same is true for our private equity proxy, which consists exclusively of private equity companies and, as no other datasets are added, is therefore considered a separate asset class.

Following the Basel IV[106] regulatory requirements, we concentrate, where possible, on European data since we assume an investor to be a European bank. Except for Dow Jones Commodity Data, all data are presented in euros. To keep the whole sample homogenous and unbiased, only total price indices are considered and total return indices are excluded. The data used in this thesis come from Thomsen Reuters Datastream and Yahoo Finance and consist of daily values over the period from October 2013 to February 2019. Our sample starts from October 2013 because cryptocurrency data, especially Litecoin, used here in this thesis, are not available for an earlier period. For all data, a minimum time

[105] See, for example, Jaggi et al. 2011, Cumming et al. 2014, Jacobs et al. 2014, Platanakis et al. 2018.
[106] Cf. Basel Committee on Banking Supervision 2019.

span of about five years should be available; only Litecoin and Bitcoin were able to provide this. For backtesting purposes, we split our sample into in-sample and out-of-sample groups, with the former starting on 2 October 2013 and ending 31 August 2018, and the latter starting on 1 September 2018 and ending 28 February 2019.

To investigate the above-mentioned alternative investment categories, we analyze the following 39 proxies:

Traditional investments

The traditional investments are represented by stocks and bonds. To keep the European restriction, we use the STOXX Europe Total Market index as proxy for stocks and the German REX for as proxy for bonds.

Dow Jones commodity futures

Dow Jones commodity future price indices were chosen as proxies for commodities. We regard the European restriction as being fulfilled since these futures are traded on exchanges in developed countries, which include European states, too.[107] The following commodities are investigated:

- Natural Gas
- Petroleum
- Wheat
- Soybeans
- Coffee
- Sugar
- Cocoa
- Cotton
- Cattle
- Lean Hogs
- Aluminum

[107] The developed country designation is based on the S&P Developed BMI index S&P Dow Jones Indices LLC 2020.

- Copper
- Lead
- Nickel
- Zinc
- Silver
- Gold

Cryptocurrencies

Cryptocurrencies are represented by Bitcoin and Litecoin. Cryptocurrency data are taken from Yahoo Finance. Only data represented in euro is used.

Private Equity

Private Equity is represented by the DAXsubsector All Private Equity & Venture Capital index. This index only includes German private equity companies, which is why it meets the European restriction.[108]

Emotional investments, energy, infrastructure, various datasets, and real estate

To account for these alternative investment categories, we chose different sub-indices of the STOXX Europe Total Market index as proxies, representing our stocks linked to alternative asset categories. We assume that the index values are directly connected to the movement of the physical alternative assets. For the models, we investigate each time series on a standalone basis. STOXX Europe Total Market indices are split into 10 industries, which are divided into 19 supersectors, 41 sectors and 114 subsectors.[109] In this thesis we focus on data at the sector level and investigate the following:

- Oil and Gas Producers (Infrastructure)
- Oil Equipment Services and Distribution (Infrastructure)
- Airlines (Infrastructure)
- Industrial Transportation (Infrastructure)
- Fixed Line Telecommunication (Infrastructure)

[108] Cf. Qontigo Index GmbH 2020.
[109] See STOXX Ltd. 2020b, p. 294 for a comprehensive overview.

- Mobile Telecommunication (Infrastructure)
- Electricity (Infrastructure)
- Gas Water and Multi-utilities (Infrastructure)
- Alternative Energy (Energy)
- Automobile and Parts (Emotional investments)
- Beverages (Emotional Investments)
- Real Estate Investments and Services (Real Estate)
- Real Estate Investments Trusts (Real Estate)
- Software and Computer Services (Other)
- Technology Hardware and Equipment (Other)
- Chemicals (Other)
- Forestry Paper (Other).[110]

For the sake of completeness, we also consider airlines, which are part of the Infrastructure category and are represented by a subsector of the sector Travel and Leisure.

As stock indices themselves belong to traditional asset classes and are sub-indices of the STOXX Europe Total Market index, our proxy for stocks, we regress the sub-indices of the STOXX Europe Total Market index and take the remaining errors as proxy for the portfolios.

[110] Cf. STOXX Ltd. 2020b, p. 295; A detailed overview about the companies within one index can be viewed on the website of STOXX Ltd. 2020a.

For coding purposes, we abbreviate the above-mentioned datasets as follows:

Title in Datastream / Yahoo Finance	Abbreviation
Dow Jones Commodity All Cattle	DJAC

Table 1: Abbreviations for the different time series

We do not analyze hedge funds in this thesis. The only price index for hedge funds that includes European data is Eurekahedge.[111] Data for this index, however, are available on a monthly and not on a daily basis. Since we analyze a five-year period, the data basis is not sufficient for models. In line with Jacobs et al.,[112] we did not find any other index for hedge funds meeting our selection criteria for a European investor. We sought to keep the dataset as homogenous as possible; therefore, we did not consider an extra data source or non-European data. Another reason for this can be attributed to Cumming et al., who emphasized that hedge fund time series may be subject to survivorship bias, which needs an adjustment too. To deal with this problem, they argued that, as their dataset contained a fund of hedge funds index, its performance would not be affected by this bias and, therefore, did not make any adjustments.[113] The index they used was non-European and consisted of monthly data. As one goal of this thesis is to provide the most homogenous dataset possible, we only accepted datasets with daily observations to avoid rescaling and the data therefore becoming a source of data manipulation.

Table 2: Overview of the 39 time series used in the thesis

The whole raw data are represented in the digital appendix of this thesis in the folder DATASETS. For the Parkinson estimator, which is explained in subsection 4.4.5.2., high and low daily prices are indicated where necessary. Therefore, we provided an extra data sheet where these data are presented. The R coding and the results for each of the following calculation steps are represented in the digital appendix of this thesis, too, in folders A-T. For illustrating purposes, we use the dataset Electricity as our illustrative thesis example.

3.1.2. Missing Data and Different Currencies

As it has two different data sources and uses both European and American exchanges and currencies, the sample faces two problems. First, missing data appear in the form of weekends and different holidays.[114] In contrast to the cryptocurrencies, which are only missing the last Sunday in October, Dow Jones, the STOXX Europe Total Market index, Rex, and DAXsubsector All Private Equity & Venture Capital provide no weekend data. Also, European and American holidays differ.[115] Second, the Dow Jones Data are represented in US dollars, while all other data are represented in euros.

The issue of missing data has been well-studied. Indeed, because data processing and analysis steps often rely on complete datasets, missing values are known to lead to several problems. As we seek to find an overall model for the 39 different time series, a comprehensive and homogenous sample is essential. Therefore, for the dataset used in this thesis, we decided to replace the missing values with reasonable values using imputation techniques, thereby avoiding inefficiencies, biases, and a non-homogenous dataset.

Much research has been carried out in this statistical field. Often cited are Rubin's[116] discourses on inference and missing data and his multiple imputation technique and Dempster's[117] Expectation-Maximization. However, besides imputation techniques, many researchers handle the missing observations as a given and treat them as equally spaced consecutive observations, irrespective of their actual spacing in time, as Datta and Du[118] or Edem et al.[119] point out. Inefficiencies and biases occur when using ad hoc methods like listwise deletion or best guess imputation. This phenomenon has been highlighted by both Datta und Du[120] and Honaker and King[121] even for political data and has been underlined by the most recent research on imputation methods using R[122] and

[114] Datastream issues the same data for every consecutive holiday. This depends on its download settings. Users receive either the same value or an NA (not applicable). For this thesis, the same value method was used. This is a known phenomenon in Datastream (cf. Erasmus University Library 2014).
[115] The missing data can be seen in the original data source.

several conference papers[123]. The focus in recent research on the weaknesses of using ad hoc methods strengthens our decision to implement an imputation technique approach.

In addition to imputation techniques, the missing data mechanism must also be taken into consideration, as Rubin already examined.[124] Missing data mechanisms can be divided into "missing completely at random" (MCAR), "missing at random" (MAR) and "not missing at random" (NMAR), as both Rubin[125] and Rubin and Little[126] have remarked. In MCAR there is no systematic mechanism that explains how data are missing. This means that the missing observations are independent of the variable values and the observation itself. In MAR, the probability of missing values is also independent of the observation itself but not independent of the point in time of the series. In NMAR, observations are not missing at random and the missing value depends on the value itself.[127] Since the missing values in this dataset depend on the point of time but not the observation itself, it is clear that MAR applies. Rubin points out that the missing data mechanism is ignorable for the MCAR and MAR case, which is why we do not take it into consideration for the imputation technique used in this thesis.[128]

The missing data problem, described above, leads to an investigation of the so-called "weekend effect" discussed in the literature. We present this here in a brief summary for the sake of completeness. The weekend effect refers to the fact that relatively large returns appear on Fridays compared to those on Mondays. This seems to be an anomaly since Monday returns span three days; one would expect higher returns on a Monday because of the longer period and the greater risk.[129] The weekend effect was recognized in 1931 by Field.[130] Half a century later, French investigated both the calendar time hypothesis, where the process of generating stock returns operates continuously and the expected return for Monday is three times the expected return for other days of the week, and the trading time hypothesis, where returns are generated only during active trading and the expected return is the same for each day of the week. He discovered that neither

[129] Cf. Sewell 2011.
[130] Cf. Fields 1931.

hypothesis was true and the average for Monday was significantly negative.[131] The negative average return on Monday was confirmed by many other authors.[132] There is similar evidence for the so-called holiday effect, suggesting that there is a tendency for the market to do well on any day which precedes a holiday.[133] This has also investigated by various authors, including Fields[134], Ariel[135], and Dzhabarov and Ziemba[136]. While these effects could lead one to favor the deletion of the missing values in the dataset used in this thesis, we will use an imputation technique as it is in line with both Datta und Du[137] and our homogenous dataset approach.

For data imputation we implement a technique already used in the literature. Moritz et al. investigated three categories of imputation techniques for univariate time series: first, univariate algorithms working with univariate inputs, like mean, mode, median or random sample, which do not employ the character of the time series; second, univariate time-series algorithms, also working with univariate inputs but making use of time-series characteristics like last/next observation carried forward or linear interpolation; and third, multivariate algorithms on lagged data. Since time is an implicit variable for time series, it is possible to add time information as covariates for applying multivariate imputation algorithms using lags and leads.[138] The authors used four different datasets (airline passengers, S&P Composite Index, daily return of Google stocks and monthly beer sales in millions of barrels) to examine the techniques. As we impute the missing values of the original dataset in this thesis, we concentrate on their S&P Composite Index results. We impute the values of the original datasets and not the missing returns for two reasons: firstly, as Moritz et al. found in their different examinations of Google stock returns,[139] it is more difficult to find an appropriate imputation method since log returns of prices are assumed to be stationary and have white noise properties; secondly, during the return calculation, we would produce at least two extra missing values per week. This is because two missing weekend data points do not allow for a correct log return calculation.

[131] Cf. French 1980.
[132] See, for example, Gibbons and Hess 1981, Jaffe and Westerfield 1985, Lakonishok and Smidt 1988, Agrawal and Tandon 1994, Rubinstein 2001, Keef et al. 2009.

[134] Cf. Fields 1934.
[135] Cf. Ariel 1990.
[136] Cf. Dzhabarov and Ziemba 2010.
[137] Cf. Datta and Du 2012.
[138] Cf. Moritz 2015, p. 8.
[139] Cf. Moritz 2015, p. 15.

Moritz et al. simulated both missing values with the MCAR mechanism and an adjustable amount of missing data. After that, they applied six appropriate R-commands (na.aggregate, na.locf, na.StructTS, na.interp, na.approx, ar.irmi from the R-packages "forecast" and "zoo") representing the three above-mentioned categories on these new created datasets. These packages are the only ones which cover both the univariate and multivariate case; otherwise, only the multivariate case is covered.[140] They evaluated their results by calculating the mean absolute percentage error (MAPE) and root mean square errors (RMSE).[141]

The authors, further, found that the command na.approx is the best fit for their examined dataset S&P Composite Index. This command uses linear interpolation.[142] Linear interpolation means that the missing value, here the price at a certain point in time, is calculated with

$$f(x_0) = f(x_1) + \frac{x_0 - x_1}{x_2 - x1}\big(f(x_2) - f(x_1)\big).$$

Here, x_0 denotes the point with the missing value; x_1 is the next given value before x_0 and has the value $f(x_1)$; and x_2 is the next given value after x_0 and has the value $f(x_2)$.[143] If two missing values appear, like on weekends, na.approx uses the next given value. Due to this, and its comparative superiority to the alternatives, we use na.approx as our imputation technique.

The command na.aggregate imputes the overall mean. Digital appendix A illustrates the large movements of our data samples. An imputation with mean and or median would, hence, not be appropriate since outliers would bias the results. The command na.lodf simply replaces the most recent non-NA, which is also inappropriate for index price data since zero movement in price data is very unlikely.[144] For seasonal data, na.StrucTS

[140] Cf. Moritz 2015, p. 13.
[141] The mean absolute percentage error between the imputed value $\bar{y}$ and the respective true value time series y: $MAPE(\bar{y}, y) \coloneqq \frac{\sum_{t=1}^{n} \frac{|\bar{y}_t - y_t|}{|y_t|}}{n}$. The root mean square error between the imputed value $\bar{y}$ and the respective true value time series y: $RMSE(\bar{y}, y) \coloneqq \sqrt{\frac{\sum_{t=1}^{n}(\bar{y}_t - y_t)^2}{n}}$. See Moritz 2015, p.12. Further information for loss functions can be found in section 4.4.5.2.
[142] Cf. Zeileis 2020, p. 22.
[143] Cf. Aubeck 2010, p. 425.
[144] Although it sometimes happens that within the dataset the same values appear, this is the exception rather than the norm.

suggests use of the seasonal Kalman filter, which is not an appropriate choice for unrecognizable patterns within the datasets. Recognizable patterns, however, are required to apply this command. The same applies for na.interp, which replaces a seasonal component of the series. Although in some cases this could be useful, at least when partial seasonality appears, Moritz et al. showed in the S&P Composite Index example that this command makes the results even worse. At least ar.irmi, coded by the authors to allow addition to the "VIM" packages, created lags to transform the dataset into a multivariate time series and apply then the irmi function, which uses step by step iteration. This algorithm also did not perform very well in S&P 500 and was therefore not chosen.[145] Digital appendix A displays the interpolated data.

Figure 1 illustrates the results for the dataset Electricity.

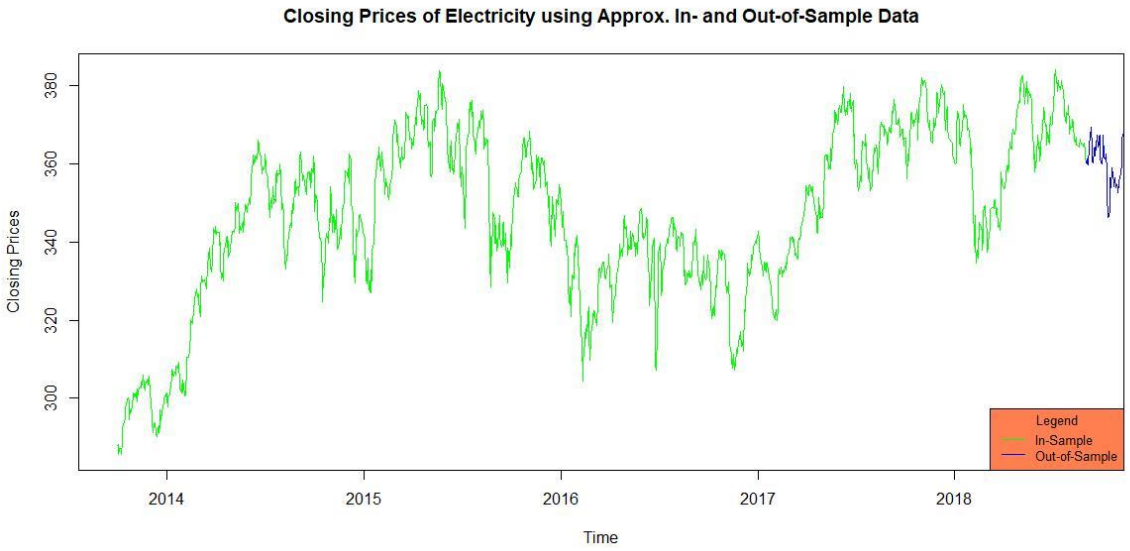

Figure 1: Closing prices of electricity using approximated in- and out-of-sample data

The graphs show that this method did not calculate any unexpectable outliers or values.

For the problem of different currencies, there are several approaches suggested in the literature. Depending on the scope of the authors, prices may or may not be converted into local currency. Chamon et al. examined in great detail whether foreign law bonds could reduce sovereign borrowing costs. As such, they especially regarded the credit risk-free currency return of foreign currencies while converting returns.[146] To account for exchange rate effects, Sukcharoen et al. converted the prices of oil and stock market

[145] Cf. Moritz 2015, p. 10f.
[146] Cf. Chamon et al. 2018.

indices too.[147] To test whether gold and silver are a hedge against inflation, Bampinas and Panagitidis converted them into local currency and showed that the hedging ability of these commodities may also be due to currency movements rather than changes in their prices per se.[148] Lucey et al. also considered this converting aspect in their work about gold and inflations.[149] A critical view on this was provided by van Hoang et al., who drew attention to misleading results regarding gold prices. In their essay about gold as a hedge against inflation, they stated that a conversion may lead to misleading results because gold prices quoted in London do not necessarily reflect the state of local gold markets or local inflations.[150] In order to find an overall model for the returns, we add to van Hoang et al.'s point and do not convert the Dow Jones Commodity datasets into the euro. This is because of two reasons: First, we want to avoid bias occurring through conversion. We want to find a model reflecting the behavior of the original dataset, which cannot be guaranteed if a conversion took place. Second, picking up on the point of van Hoang et al., a conversion blurs the price and market behavior.

3.1.3. Return Calculation and Descriptive Measures

As the data we work with in the thesis are not related to price but the calculated return, we explain here how we calculated the returns. For a better understanding of the data, we also provide the descriptive measures of the returns in this chapter.

For given stock prices p_t with $t = 0,1, \dots T$, the return of one period is defined as the change rate of the prices from $t-1$ to t. Therefore, the return R_t for $t = 0,1, \dots T$ is

$$R_t = \frac{p_t - p_{t-1}}{p_{t-1}} = \frac{p_t}{p_{t-1}} - 1.$$

R_t is a discrete return with $-1 \leq R_t \leq \infty$, which means that the worst loss is the total loss of -100%. An advantage of this definition is that the return of a portfolio is the weighted sum of the returns of all portfolio instruments. Next to the discrete return, the definition of continuous return is represented by

$$r_t = ln\left(\frac{p_t}{p_{t-1}}\right) = \ln(p_t) - \ln(p_{t-1}),$$

with

$$r_t = \ln(R_t + 1)$$
$$R_t = e^{r_t} - 1.$$

This relationship is a result of the first order Taylor-approximation, defined by

$$f(x) = f(x_0) + f'(x_0)(x - x_0) + o(x - x_0),$$

with $o(x - x_0)$ as the approximation error given by $\lim_{x \to x_0} \frac{o(x-x_0)}{(x-x_0)} = 0$.

When $f(x) = l(x)$ and $x = \frac{p_t}{p_{t-1}}$, for the Taylor approximation at $x_0 = 1$,

$$ln\left(\frac{p_t}{p_{t-1}}\right) = \frac{p_t}{p_{t-1}} - 1 + o\left(\frac{p_t}{p_{t-1}} - 1\right)$$

and

$$r_t = R_t + o\left(\frac{p_t}{p_{t-1}} - 1\right)$$

hold.

The difference between both is, therefore, almost negligible. We use daily data where the choice of return calculation is irrelevant since prices rarely vary from one day to another.[151] However, we decided to use the compound opportunity due to the dataset's stationarity[152] as other researchers in the field of financial time series.[153]

Digital appendix B presents graphs of the time series' returns. As an example, figure 2 below displays below the log-returns for the STOXX Europe Total Market Electricity Index:

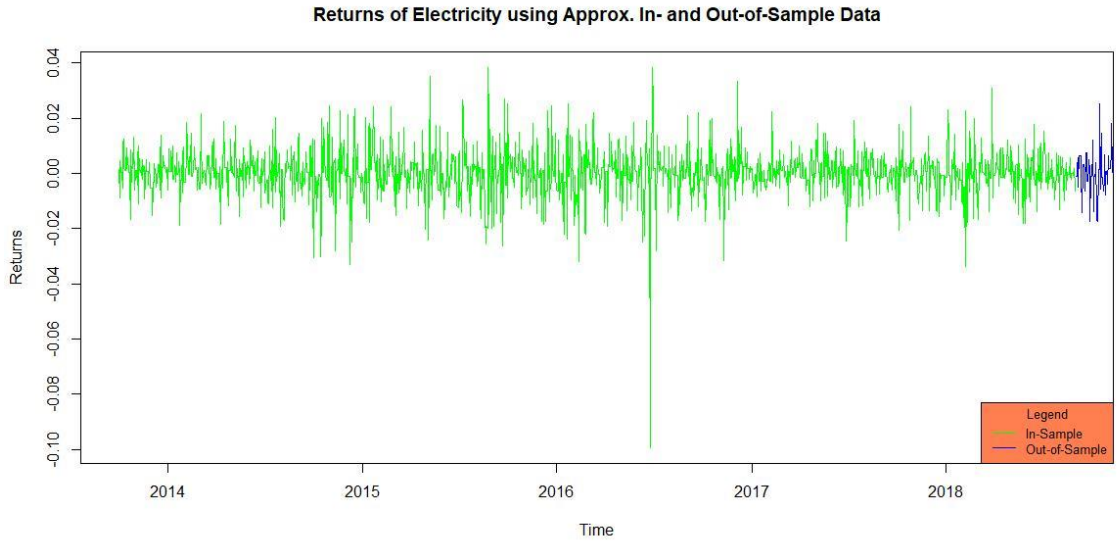

Figure 2: Returns of electricity using approximated in- and out-of-sample data

For the European data, it is noteworthy that outliers appear in the middle of 2016. This is a consequence of the Brexit decision in Great Britain on 23 and 24 June 2018. In addition,

[151] Cf. Schmid and Trede 2006, p. 3ff; parameters of the introduced formulas are harmonized to the parameters used generally within this thesis.
[152] See section 4.2.
[153] See, for example, Cumming et al. 2014, Troster et al. 2018, Shakil et al. 2018, Szumilo et al. 2017, Baur and McDermott 2010.

the price of gold increased, a movement that is recognizable on the gold return chart. Hence, these outliers are explainable and, as such, have not been removed.

Digital appendix C illustrates the summary statistics of the datasets in terms of median, mean, quantiles, variance and standard distribution.

Some main results of the descriptive statistics are, in terms of the thesis, worthwhile mentioning. First, Bitcoin and Litecoin provide both the highest (0.7751 and 0.773201) and lowest (-0.58526 and -0.618224) returns of the whole sample set. Additionally, both provide the highest variance und standard distribution. Both time series also provide the highest return means. This confirms large movements for the volatility and return structure within the cryptocurrencies returns that are significantly higher than the other datasets. Oil, equipment services and distribution have the lowest mean (-0.0004179) and minimum loss (-0.009399). REX displayed the lowest variance and standard deviation, underlining the safe nature of bonds. Additionally, of note is that Litecoin and Bitcoin's maximum returns are followed by coffee, natural gas and zinc, alternative energy, petroleum, sugar, and nickel, all of which belong to the Dow Jones commodity index. Excepting petroleum, coffee, alternative energy, and natural gas, the time series are not associated with the highest levels of variance for the whole sample, as was the case for Litecoin and Bitcoin.

The large differences in the volatility of the data could initially discourage the idea of a comprehensive GARCH model. Nevertheless, we stick to our assumption that this is still possible. We, therefore, rely on the well-studied and so-called stylized facts about financial time series, presented in chapter 3.2.2. Cont pointed out that more than half a century of empirical studies in financial time series show that, from the statistical point-of-view, properties of commodity futures, shares or exchange rates are similar.[154] As such, despite the large volatility movement in the data sets, we remain with our comprehensive model approach.

For further analysis, knowledge of the return distribution is useful. We first test our data for the well-known normal distribution, meaning the probability is high that an observation will be close to the average and low that it will be far away. To do so, we

[154] Cf. Cont 2001.

analyze skewness and kurtosis of the data, and carry out the Jarque-Bera test. A distribution is said to be positively skewed if there are more extreme returns on the right tail and negatively skewed if there are more extreme returns on the left.[155]

The degree of skewness is measured with the Fishers skewness formula:

$$Skewness\ S = \frac{1}{T}\sum\left(\frac{r_t-\bar{r}}{\sigma}\right)^3,$$

where $\bar{r}$ is the mean return and σ is the standard deviation. To consider the sample size, the term $\frac{1}{T}$ changes to $\frac{T}{(T-1)(T-2)}$. The sample skewness then becomes

$$Skewness\ S_S = \frac{T}{(T-1)(T-2)}\sum\left(\frac{r_t-\bar{r}}{\sigma_s}\right)^3,$$

with σ_s as the sample standard distribution that is used here. A normal distribution has a skewness of zero. Therefore, positive values indicate a right-skewed and negative values a left-skewed distribution.[156]

Kurtosis measures the weight of returns in the tails of the distribution relative to standard deviation and is associated with the return distribution's flatness or peakedness. The Pearson's kurtosis is defined by $Kurtosis\ K = \frac{1}{T}\sum\left(\frac{r_t-\bar{r}}{\sigma}\right)^4$, while the sample Kurtosis includes again an adjustment term for the sample size, which leads to

$$Kurtosis\ K_S = \frac{T(T+1)}{(T-1)(T-2)(T-3)}\sum\left(\frac{r_t-\bar{r}}{\sigma_s}\right)^4.$$

Normally distributed data have a kurtosis near three and are termed as mesokurtic. Therefore, excess kurtosis is calculated by subtracting three, which leads to

$$Excess\ Kurtosis\ K_E = \frac{1}{T}\sum\left(\frac{r_t-\bar{r}}{\sigma}\right)^4 - 3$$

[155] Cf. Bacon 2008, p. 82f.
[156] Cf. Bacon 2008, p. 84; parameters of the introduced formulas are harmonized to the parameters used generally within this thesis.

and

$$K_{SE} = \frac{T(T+1)}{(T-1)(T-2)(T-3)} \sum \left(\frac{r_t - \bar{r}}{\sigma_s} \right)^4 - \frac{3(T-1)^2}{(T-2)(T-3)},$$

respectively, for the sample. The variance of a distribution is called the second moment of the mean, skewness the third and kurtosis the fourth.[157]

This knowledge of skewness and kurtosis allows for the testing of the normal distribution. The Jarque-Bera statistics are calculated by

$$JB = \frac{T}{6} \left(S^2 + \frac{K_E^2}{4} \right).$$

The assumption of a normal distribution is rejected if the test statistics exceeds 5.99 at a 5% and 9.21 at a 1% confidence level. Perfectly normal distributed data have a JB value of zero.[158]

The results for kurtosis, skewness and JB statistics are also presented in digital appendix C. The results of the table show clearly that the return data are not normally distributed since the JB test statistics exceed the theoretical values in every case. This is highlighted by the fact that excess kurtosis is always positive, an indicator of leptokurtic distribution. The results are underlined by QQ-plots for normal distribution presented in digital appendix D. Owing to the leptokurtic components of the time series, we also provide QQ-plots for Student's t-distribution[159] in digital appendix E; its higher peaks and fatter tails[160] display a much better fit for the whole sample. For example, figure 3 shows the QQ-plot for normal distribution for the log-returns for STOXX Europe Total Market Electricity Index, and figure 4 displays the Student's t-distribution:

[157] Cf. Bacon 2008, p. 84f.
[158] Cf. Bacon 2008, p.8.
[159] The function TQQPlot in R does not allow the addition of a title. Please note that the relevant dataset is indicated by title of the graph files.
[160] Cf. Bauwens et al. 2012, p. 108.

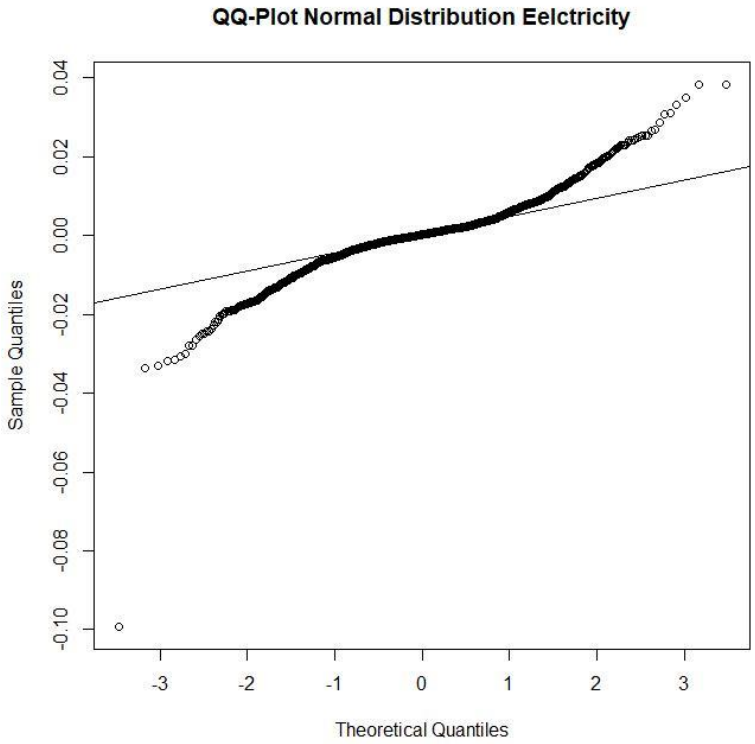

Figure 3: QQ-plot of normal distribution for electricity

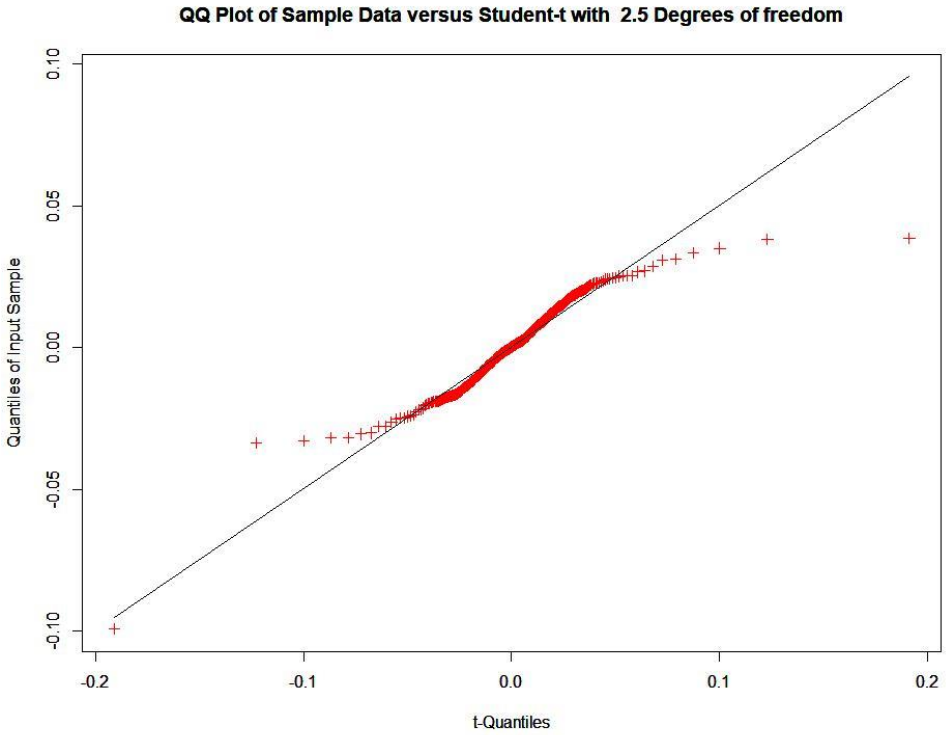

Figure 4: QQ-plot of Student's t-distribution for electricity

Figure 3 illustrates that even the best-fitted normal distribution does not provide a good fit to the reference distribution. The empirical distribution of the daily returns has significantly heavier tails than those of the reference distribution. In contrast, figure 3 indicates a much better fit as the empirical distribution has slightly lighter tails and only a few points are off the linear line. All datasets had a Student-t distribution, except for Bitcoin and Litecoin. The following graphs illustrate how their distributions differed:

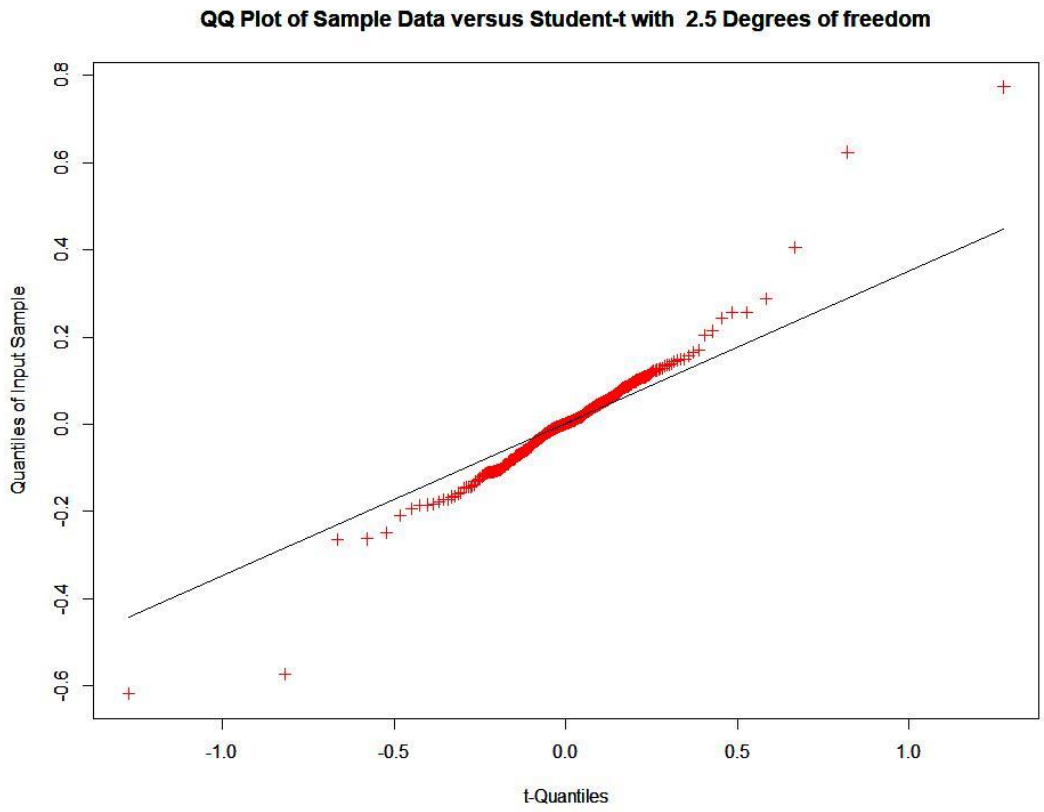

Figure 5: QQ-Plot of Student's t-distribution for Bitcoin

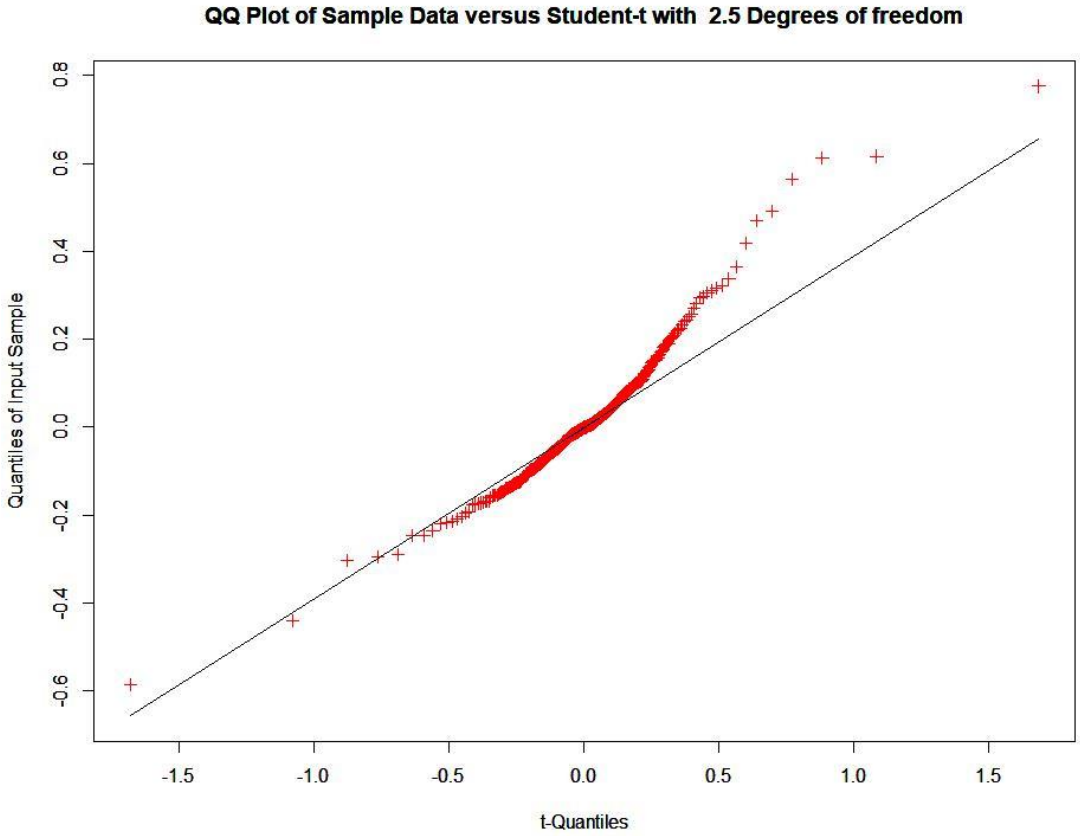

Figure 6: QQ-Plot of Student's t-distribution for Litecoin

3.2. Methodology

3.2.1. Methodology Overview

After introducing our dataset, this chapter is devoted to the methodology employed for our further data analysis. We, therefore, first explain the methodology that we use for our investigations. Following this, we describe the stylized facts of financial time-series data, which are necessary to understand and justify the choice of our statistical methods. In chapter 4 we present the theoretical statistical background needed for the methodology. Finally, at the end of each theoretical section in chapter 4, we provide a brief summary of our results for that specific method, to which we give the title "Conclusion Based on Empirical Findings".

Our methodological approach was the following: firstly, we tested our data for stationarity as this condition was necessary for all further data calculation; secondly, we tested the descriptive power of autoregressive moving average (ARMA) and GARCH models for the following heuristic; thirdly, carried out backtesting and evaluated the models.

To ensure stationarity for our data, we conducted three tests: the Dickey Fuller Test, the Philipp and Perron Test, and the KPSS Test. We tested all three since one test alone is too susceptible to erroneous results.

Based on a strong understanding of white noise, autoregressive, and moving average processes, we examined whether an ARMA model was necessary for our financial log return data. For this, we conducted the Ljung-Box test, additionally applying the autocorrelation function (ACF) and the partial autocorrelation function (PACF).

ARMA models alone were not able to describe our data well.[161] Hence, we explored GARCH models as alternatives. To do so, we first examined the different kinds of GARCH models with normal (nor), Student's t- (std) and general error distributions (ged). Our GARCH model and distribution selection were motivated by several approaches in the literature: Ekong and Onye[162] tested GARCH(1,1), EGARCH(1,1), TGARCH(1,1), augmented GARCH(1,1), augmented EGARCH(1,1), and augmented TGARCH(1,1), in combination with normal, Student's t- and ged distribution, and found that an augmented

[161] See footnote 251 for more information.
[162] Cf. Ekong and Onye 2017.

EGARCH (1,1) model with ged performed best; Chu et al. used twelve varying GARCH(1,1) models with eight different innovation processes, including all of our chosen ones (with exception to ged), and found that, with normal distributions, IGARCH(1,1) and GJR-GARCH(1,1) performed best for different cryptocurrency data;[163] Troster et al. investigated eight GARCH(1,1) models with conditional means and five different innovation distributions. They compared them to generalized autoregressive score (GAS) models and found that normally distributed GARCH models are always outperformed by heavy-tailed GARCH or GAS models.[164] Due to the results of the above-named authors, we included EGARCH, IGARCH, and GJR-GARCH. For the sake of completeness, we also included a standard GARCH and component standard GARCH (CSGARCH). These models are described in detail in subsection 4.4.1.

To evaluate whether GARCH models were applicable to our time series, we introduced the Engle's Lagrange-Multiplier test and went deeper into the analysis of squared returns. For parameter estimation we used the quasi-maximum-likelihood.

In line with the investigation approach of Hansen and Lunde[165], we not only tested p,q=(1,1) for the models but also (1,1), (1,2), (2,1), and (2,2). This led to at least 60 models tested per dataset (five different variance models with four different p,q orders, three different error distribution terms and one constant individual mean model if it was necessary), providing 39 x 60 results.

For the model evaluation and backtesting of the 2340 results, we investigated the significance and persistence of the model parameter for each model. Backtesting was carried out using the method of McNeil and Frey.[166] This method requires that the estimated expected shortfalls and value at risks are calculated from both the forecasted data and actual out-of-sample data. We therefore needed the forecasted sigma values for 181 days (the length of our out-of-sample time window) for each of the remaining GARCH models. To do this, we introduced the calculation method for the value at risk and expected shortfall for Student's t- and normal distributions. Hence, we tested the

[163] Cf. Chu et al. 2017.
[164] Cf. Troster et al. 2018.
[165] Cf. Hansen and Lunde 2005.
[166] Cf. McNeil and Frey 2000.

backtest of McNeil and Frey for both distributions too. For the last evaluation step, we used the Akaike information criterion.[167]

For the sake of completeness, we also explored loss functions and GARCH model diagnostics. This included, for example, mention of the ARCH-LM test, Sign Bias, Ljung-Box Residuals test, and the Goodness of fit, but these were not a main focus for our judgment.

To answer the third research question, we created portfolios: we understood and created the portfolios as new univariate time series by adding and weighting the different asset classes into subgroups. As mentioned in section 3.1, the 39 time series were taken from different asset classes. To account for these asset classes, we clustered similar financial time series, as they are presented in table 2 of subsection 3.1.1, into different asset-class groups. As infrastructure and commodities would contain many more datasets than the other asset classes, we decided here to create several additional subgroups. Asset classes and subgroups were then created as follows:

- Traditional Investments (REX and STOXX Europe Total Market Index); Subgroup 1
- Commodities
    - Food ; Subgroup 2
    - Energy; Subgroup 3
    - Metal; Subgroup 4
    - Cotton; Subgroup 5
- Cryptocurrencies; Subgroup 6
- Private Equity; Subgroup 7
- Stocks linked to alternative asset categories
    - Emotionals; Subgroup 8
    - Energy; Subgroup 9
    - Infrastructure
        - Oil; Subgroup 10
        - Telecommunication; Subgroup 11
        - Transport and Utilities; Subgroup 12

[167] This is in line with, for example, Chu et al. 2017, Glaser et al. 2014, Kawaguchi et al. 2017, Troster et al. 2018.

- Other; Subgroup 13
- REITS; Subgroup 14.[168]

Subgroup 1 represented the portfolio of traditional investments. Subgroups 2-14 represented the different alternative asset classes. The datasets within Subgroups 2-14 were equally weighted, which is in line with one of the three approaches used by Jacobs et al.[169] or the single approach of Daigler et al.[170] In contrast to Jacobs et al.[171] and the weighting schemes of Jaggi et al.,[172] our traditional portfolio (subgroup 1) comprised 82.1% bonds and 17.9% equities and did not contain any other assets. These percentages were derived from Deutsche Bundesbank's statistical bank data by taking the values of bonds and equities and calculating their ratios.[173] Since we wanted to provide results with practical relevance, we decided to create the traditional portfolio out of real numbers. We, therefore, established the mixed portfolios in the following way: firstly, we investigated subgroup 1 on a standalone basis since this portfolio represents the reference portfolio to which we compared the other portfolios of subgroup 2-14; secondly, we created the mixed portfolios of traditional and alternative asset classes by reducing the 17.9% of equities and added, in case A, 8.95% of a subgroup (which is the mean of the equity part), in case B, 5%, C, 3%, and D, 1%. We, hence, created one traditional and 13 x 4 mixed portfolios:

- Traditional investment portfolio (reference portfolio): 82.1% of bonds and 17.9% of equities
- Portfolio type A: 82.1% bonds + 8.95% equities + 8.95% subgroup
- Portfolio type B: 82.1% bonds + 12.9% equities + 5% subgroup
- Portfolio type C: 82.1% bonds + 14.9% equities + 3% subgroup
- Portfolio type D: 82.1% bonds + 16.9% equities + 1% subgroup

Knowing well that subgroups 8-14 are sub-indices of the STOXX Europe Total Market Index, we regressed the sub-indices on this index. Additionally, we assumed the residuals of this linear regression to be an adjusted time series to avoid overweighting. For the sake

[168] The weighting scheme of each subgroup and the exact coding of the portfolios is represented in digital appendix T.

[170] Cf. Daigler et al. 2017.
[171] Cf. Jacobs et al. 2014.
[172] Cf. Jaggi et al. 2011.
[173] Cf. Bundesbank 2019. We took positions 11 (Bonds: 951.522) and 12 (Equities: 207.891) from August 2018 as this corresponded to our in-sample period.

of completeness, we took both the portfolios with overweighting and the portfolios with residuals into consideration.

We then repeated all calculation steps on the portfolios and compared the 13x4 portfolios and 8x4 portfolios on a regression basis to our reference portfolio in terms of expected shortfall. We, therefore, built the average of all forecasted expected shortfalls on the out-of-sample horizon and compared these to subgroup 1's reference portfolio. To build the average is possible since we assume independent and identical (iid) samples. To answer the last research question, we also proved whether the comprehensive GARCH model was applicable to the mixed portfolios.

For all calculations, we primarily used R's rugarch package.[174]

3.2.2. Stylized Facts

The investigation of financial time series is mainly a study of volatility. One assumption inherent to our research questions is that all our chosen asset classes have similar statistical characteristics. Otherwise, the investigation of one comprehensive GARCH model for all financial time series would not be possible. This assumption is based on and justified by the so-called stylized facts of financial time series, which have emerged from intensive studies on the behavior of financial time series. Accordingly, we present a brief literature overview and provide the most important stylized facts. The following chapters investigate in detail the existence of these stylized facts within our dataset, focusing particularly on the conclusions based on empirical findings.

As evidenced by Merton's[175] study in 1969 and Black and Scholes'[176] in 1973, early theoretical models in the literature assumed constant volatility. Further investigation, however, led to the now well-studied fact that the volatility of asset returns is time-varying and predictable, as Andersen and Bollerslev pointed out in 1997.[177] Moreover, Engle and Patton showed that volatility is mean-reverting and exhibits persistence, and that innovations have an asymmetric impact on volatility.[178]

[174] Cf. Ghalanos 2020.
[175] Cf. Merton 1969.
[176] Cf. Black and Scholes 1973.
[177] Cf. Andersen and Bollerslev 1997.
[178] Cf. Engle and Patton 2001.

Malmsten and Teräsvirta discovered more stylized facts in their paper on stylized facts of financial time series. Firstly, they illustrated that the combination of relatively high kurtosis and rather low autocorrelations of squared returns is typical for a large amount of return series. Secondly, they introduced the Taylor effect, meaning that autocorrelations are larger for absolute returns than for squared ones (see Granger and Ding[179] and Granger et al.[180]). They designated the very slow decay rate of autocorrelations as a stylized fact but showed that this is not typical for series with a couple of thousand observations, which is not the case in this thesis. [181] Chakraborti et al. added to this last point by stating that it is already well known as "volatility clustering". They further highlighted that asset returns admit heavier tails than the normal distribution.[182]

Cont summarized stylized facts as properties that are common across a wide range of instruments, markets and time periods. He pointed out that more than half a century of empirical studies in financial time series show that, from the statistical point-of-view, properties of commodity futures, shares or exchange rates are similar.[183]

All points listed above of course did not include cryptocurrencies as cryptocurrencies represent a new research field. However, we found evidence in Philipp, Chan and Peiris[184] and Da Cunha and Da Silva[185] that the most presented stylized facts are valid for cryptocurrencies too. Philipp, Chan and Peiris found that Bitcoin contains many stylized facts, including long memory, heteroskedasticity and heavy tailedness. They further discovered that cryptocurrencies, in general, have several unique properties, including leverage effects and Student's t-error distributions.[186] Da Cunha and Da Silva investigated whether the same stylized facts found in traditional financial assets also hold for Bitcoin. They concluded that it behaves statistically in the same way as most other assets. However, their most important conclusion was three-fold: the logarithmic returns of Bitcoin exhibit fat tails; Bitcoin returns display aggregational Gaussianity and its

[186] Cf. Phillip et al. 2018.

volatility tends to cluster in time; and the correlation between the volume and long-range returns predict the structure better than the other way around.[187]

We, therefore, apply the same mechanisms on cryptocurrencies as on the other asset classes and consider our approach of utilizing a uniform heuristic procedure for all financial time series to be justified.

4. Theoretical Background and Empirical Results

4.1. Stochastic Processes

This chapter outlines the theoretical background for the methodology described in section 3.2. First, we introduce the principles of a stochastic process. Following this, we discuss the concept of stationarity. As it will be important for the volatility models, we further introduce linear stochastic processes. We then explain the volatility models and, furthermore, explain the concepts of value at risk, expected shortfall, and the backtesting procedure. Every section within this chapter ends with a conclusion summarizing the empirical results derived from our sample.

A sequence of random variables $x_1, x_2, x_3, \ldots$, where x_1 is the value of t_1 and x_2 is the value of t_2, is considered to be a time series. A collection of random variables x_t with index t, is a stochastic process $(X_t)_{t\in\mathbb{T}}$. Typical for economic time series is that $\mathbb{T}$ is discrete and and t varies over the integers $t = 0, \pm1, \pm2, \ldots$, or a finite subset of the integers.[188] The function $t \rightarrow X_t$ is a path of (X_t). A realization or trajectory is denoted with $t \rightarrow x_t$. A time series then is denoted as both the realization or trajectory and the underlying stochastic process.[189] Following the Kolmogorov theorem, a stochastic process is clearly defined if a system of its finite-dimensional distribution function is known. The full specification of all moments is too complex in most cases, which is why the focus lies on the first two moments of the distribution. These are given by the expectation value

$$\mathbb{E}X_t = \mu_t$$

and the variances

$$\mathbb{V}X_t = \sigma_t^2,$$

with $t \in \mathbb{Z}$, as well as by the covariances

$$cov(X_t, X_s) = \mathbb{E}(X_t - \mathbb{E}X_t)(X_s - \mathbb{E}X_s) = \mathbb{E}(X_t X_s) - \mathbb{E}X_t\mathbb{E}X_s$$

[188] Cf. Shumway and Stoffer 2011, p. 11, Neusser 2011, p. 8.
[189] Cf. Neusser 2011, p. 9.

and correlations

$$corr(X_t, X_s),$$

with $t, s \in \mathbb{Z}$.[190]

4.2. Stationarity and Stationary Statistical Key Figures

4.2.1. Concept of Stationarity

For further analysis, we introduce the concept of stationarity, as it is necessary for the application of GARCH models. Stationarity naturally replaces the hypothesis of iid observations in standard statistics.[191] Time-series analysis assumes that realizations of a stochastic process depend on different points of time; this dependence is described by covariances and correlations. As one datapoint can depend on more than one past value, an infinite number of covariances are possible. We introduce the covariance and correlation function to describe all covariances between a finite number of random variables.[192]

If the variance of a stochastic process (X_t) is finite, the so-called autocovariance function is represented by

$$\gamma_x(t, s) = cov(X_t, X_s) = \mathbb{E}[(X_t - \mu_t)(X_s - \mu_s)]$$

for all s and t, where $\gamma_x(s, t) = \gamma_x(t, s)$ for all time points s and t. The autocovariance function measures the linear dependency between two points of the same series at different point of time.[193] A more convenient measure is the autocorrelation function (ACF):

[190] Cf. Neusser 2011, p. 9; Neusser did not introduce μ and σ. To keep the notations consistent with those of Shumway μ and σ are introduced here.
[191] Cf. Francq and Zakoian 2010, p. 1, Neusser 2011, p. 10.
[192] Cf. Neusser 2011, p. 10.
[193] Cf. Shumway and Stoffer 2011, p. 19.

$$\rho(s,t) = \frac{\gamma(s,t)}{\sqrt{\gamma(s,s)\gamma(t,t)}},$$

resulting in values between -1 and 1. The ACF measures the linear predictability of the series at time t. A perfect prediction of x_t from x_s by the linear relationship $x_t = \beta_0 + \beta_1 x_s$ would lead to a correlation of $+1$ when $\beta_1 > 0$ and -1 when $\beta_1 < 0$, providing $-1 \leq \rho(s,t) \leq 1$.[194]

In a strictly stationary time series, the probabilistic behavior for every collection of values $(x_{t1}, x_{t2}, \dots, x_{tk})$ is identical to that of the time shifted set $(x_{t1+h}, x_{t2+h}, \dots, x_{tk+h})$ which means $P(x_{t1} \leq c_1, \dots, x_{tk} \leq c_k) = P(x_{t1+h} \leq c_1, \dots, x_{tk+h} \leq c_k)$ for all $k = 1,2, \dots$, all time points $t_1, t_2, \dots, t_k$, all numbers $c_1, c_2, \dots, c_k$, and all time shifts $h = 0, \pm 1, \pm 2, \dots$.[195] The properties are unaffected by a change of time origin.[196] For most applications this assumption is too strong. Hence, the milder concept of weak stationarity is more convenient since this concept only affects the series' first two moments. A weakly stationary time series, (X_t), is a finite variance process in that the mean value μ_t is constant and does not depend on t. Also, the autocovariance function $\gamma(s,t)$ depends on s and t only through their difference $|s-t|$. The time difference between $t+h$ is the same as the difference between times h and 0 and, thus, the autocovariance and autocorrelation functions do not depend on time argument t. We will use the term stationary now as the synonym for weak stationary.

The autocovariance function of a stationary time series is, hence, given by

$$\gamma(h) = cov(X_{t+h}, X_t) = \mathbb{E}[(X_{t+h} - \mu)(X_t - \mu)]$$

and the autocorrelation function (ACF) of a stationary time series by

$$\rho(h) = \frac{\gamma(t+h,t)}{\sqrt{\gamma(t+h,t+h)\gamma(t,t)}} = \frac{\gamma(h)}{\gamma(0)}.$$[197]

[194] Cf. Shumway and Stoffer 2011, p. 21.
[195] Cf. Shumway and Stoffer 2011, p. 20f.
[196] Cf. Mills and Markellos 2008, p. 11.
[197] Cf. Shumway and Stoffer 2011, p. 22ff.

In practical statistics, the preceding theories must be applied to sampled data $x_1, x_2, \dots, x_n$, which causes a problem due to the absence of iid copies of (X_t) that are available for estimating the covariance and correlation functions. If a time series is stationary, the mean function $\mu_t = \mu$ is constant and can be estimated by the sample mean

$$\bar{X} = \frac{1}{n}\sum_{t=1}^{n} X_t.$$

The standard error of an estimate is the square root of $var(\bar{x})$, which is given by

$$var(\bar{X}_t) = var\left(\frac{1}{n}\sum_{t=1}^{n} X\right) = \frac{1}{n^2}\, cov\left(\sum_{t=1}^{n} X_t, \sum_{s=1}^{n} X_s\right)$$

.

The sample autocovariance function is defined as

$$\hat{\gamma}\,(h) = \frac{1}{n}\sum_{t=1}^{n-h}(X_{t+h} - \bar{X})(X_t - \bar{X})$$

with $\hat{\gamma}\,(-h) = \hat{\gamma}\,(h)$ for $h = 0,1, \dots, n-1$. The sum runs over a restricted range since X_{t+h} is not available for $t + h > n$. The sample autocorrelation function is given by

$$\hat{\rho}(h) = \frac{\hat{\gamma}\,(h)}{\hat{\gamma}\,(0)}.$$ [198]

[198] Cf. Shumway and Stoffer 2011, p. 28f.

4.2.2. Testing for Stationarity

4.2.2.1. Dickey-Fuller-Test

Since the absence or presence of stationarity is crucial for the right model choice, a test for stationarity of the data is required. Therefore, we introduce the firmly established[199] tests of Dickey and Fuller[200], Philipp and Perron[201], and Kwiatowski[202]. Each of these tests has its weaknesses, and there is no optimal method applicable to every time series in general.[203] For this reason, we utilize all three tests in this thesis.[204]

The Dickey-Fuller test is based on an autoregressive model for the time series (X_t) that is to be examined. This is denoted as $X_t = \rho X_{t-1} + \varepsilon_t$[205], where $X_0 = 0, \rho$ is in this subsection represents a real number and ε_t a sequence of independent normal random variables with mean 0 and variance σ^2.[206] It is possible for some deterministic variables, i.e., a constant α or deterministic trend δ_t, to be added.[207] In the following section, this autoregressive model is termed the "Dickey-Fuller regression". In order to test for stationarity, the authors test the null hypothesis that a unit root exists by testing whether $\rho = 1$, under the assumption $\rho = \pm 1$.[208] For the unit root test, there are two types of possible tests: the Dickey-Fuller and the augmented Dickey-Fuller. Two possible test statistics are given, which are applicable for both tests. The first is commonly termed the ρ-test $T(\hat{\rho} - 1)$, which is asymptotically not normally distributed. The values for this statistic are, therefore, set out in the following a tabular form:

[199] Cf. Horváth et al. 2014, p. 56.
[200] Cf. Dickey and Fuller 1979.
[201] Cf. Phillips and Perron 1988.
[202] Cf. Kwiatkowski et al. 1992.
[203] Cf. Möller 2003, p. 57.
[204] In financial research, most authors only use one or two tests. Some other authors also use three (e.g. Shakil et al. 2018). Since this thesis is a complete analysis of the data, all three tests are used.
[205] Here, Dickey and Fuller used y_t instead of x_t and e_t instead of ε_t. To ensure consistency with the other chapters, the y_t is changed to x_t and e_t is changed to ε_t. We kept the ρ of Dickey and Fuller here as we need the commonly termed ρ-test statistics (Neusser 2011, p. 121) for this test. Therefore, only in this subsection dealing with stationarity does ρ represent a real number and not the autocorrelation function.

Table 4: Critical values for $t_{\hat{\rho}} = \frac{(\hat{\rho}_T - 1)}{\hat{\sigma}_{\hat{\rho}}}$ [210]

[210] Cf. Banerjee 1993, p. 104; the positive and negative numbers are a result of the skewness of the sample distribution.

The limit distribution of the ρ- and t -statistics depend on the deterministic components and the true data-generating process, which leads to the use of different sections of the tables depending on those specifications.[211] An overview of the use of the required statistics is given in table 5.

True data generating process (null hypothesis)	Estimated Dickey-Fuller-Regression	ρ-test $T(\hat{\rho}-1)$	t-Value
$X_t = X_{t-1} + \varepsilon_t$	$X_t = \rho X_{t-1} + \varepsilon_t$	Case 1	Case 1
$X_t = X_{t-1} + \varepsilon_t$	$X_t = \alpha + \rho X_{t-1} + \varepsilon_t$	Case 2	Case 2
$X_t = \alpha + X_{t-1} + \varepsilon_t, \alpha \neq 0$	$X_t = \alpha + \rho X_{t-1} + \varepsilon_t$		$N(0,1)$
$X_t = \alpha + X_{t-1} + \varepsilon_t$	$X_t = \alpha + \delta_t + \rho X_{t-1} + \varepsilon_t$	Case 4	Case 4

Table 5: Different cases for the correct choice of critical values[212]

In case 1, the Dickey-Fuller regression has no constant. A rejection of the null hypothesis implies that (X_t) is a stationary process with a mean of zero. Hence, this is more a theoretical than practical process since the used data must, surely, have a mean of zero, something which is not given in most cases. This is why plotting the data first is recommended to identify whether the data could have a mean of zero or a trend. For data without a trend, the Dickey-Fuller regression with a constant (case 2) should be considered. A rejection of the null hypothesis implies that (X_t) is a stationary process with a mean $\mu = \frac{c}{1-\rho}$, where c denotes a constant. For data with a trend, the Dickey-Fuller regression should include a trend next to the constant; this is considered in case 4. A rejection of the null hypothesis implies that (X_t) is a trend stationary process. Purely of theoretical interest is the case of asymptotic normality; however, this only becomes important when the Dickey-Fuller regression has no trend, and under the null hypothesis a trend is given. It should be a priori clear whether the data imply a trend or not, e.g., when plotting the data first. This case is mentioned here, too, for the sake of completeness.

[211] Cf. Neusser 2011, p. 121.
[212] Cf. Neusser 2011, p. 122.

Due to the high autocorrelation of most of the economic time series, it is necessary to include lagged differences $\Delta X_{t-1}, \dots, \Delta X_{t-p+1}$, where p represents the order of the model.[213] The Dickey-Fuller regression then turns to $\Delta X_t = \alpha + \delta t + \rho X_{t-1} + \vartheta_1 \Delta X_{t-1} + \cdots + \vartheta_{p-1} \Delta X_{t-p+1} + \varepsilon_t$. This test is called the "Augmented Dickey-Fuller test" (ADF-test). The limited distribution of the ADF-test does not change with the autoregressive correction. For the coefficients of the correcting terms, the standardized t-test and F-test tables can be used here. The choice of the lag parameter p depends on the residuals; they should turn to white noise. A consistent strategy of finding the right lag order is the minimization of the AIC criterium.[214] Dickey and Fuller suggest calculating the order as a function of the number of observations n.[215]

4.2.2.2. Philipp and Perron Test

Philipp and Perron established an alternative strategy to consider the autocorrelation within the data. Therefore, the OLS-estimators, in particular the t-value, are corrected in a nonparametric way. Consider the Dickey-Fuller-Regression without the autoregressive correcting terms $X_t = \alpha + \delta t + \rho X_{t-1} + \varepsilon_t$, where ε_t here does not have to be a white noise process[216] but a general stationary process with an expected value of zero. First, X_t is regressed against X_{t-1} and the potential deterministic components. Second, a long-run variance $J = \lambda(0) + 2\sum_{h=1}^{\infty} \lambda(h)$ is estimated out of the residuals (ε_t).[217] The unconditional variance of (ε_t) is denoted as $\lambda_\varepsilon(0)$ and is estimated via $\widehat{\lambda_\varepsilon}(0)$. These two variances are used to modify the value of ρ respectively t of $\widehat{\rho_T}$. If no deterministic variables are taken into consideration (case 1 of table 5) the modified test-statistics are given through this formula:

$$\rho - Test: \qquad T(\hat{\rho} - 1) - \frac{1}{2}\left(\widehat{J_T} - \widehat{\lambda_\varepsilon}(0)\right)\left(\frac{1}{T^2}\sum_{t=1}^{T} X_{t-1}^2\right)^{-1}$$

[213] Cf. Neusser 2011, p. 122f.
[214] Cf. Neusser 2011, p. 122; the Akaike information criterion is explained in subsection 4.4.5.1.
[215] Cf. Said and Dickey 1984, p. 599.
[216] White noise processes are explained in subsection 4.3.1.
[217] Cf. Neusser 2011, p. 123; for more information on the estimation of $\widehat{J_T}$, see Neusser 2011, p. 46ff. The KPSS-test in the following subsection outlines the Newey-West estimator for this, which was also suggested in the original paper of Phillips and Perron 1988 p. 340.

$$t-Test: \qquad \sqrt{\frac{\widehat{\lambda_\varepsilon}(0)}{\widehat{J_T}}}\, t_{\hat{\rho}} - \frac{1}{2}\left(\widehat{J_T} - \widehat{\lambda_\varepsilon}(0)\right)\left(\frac{\widehat{J_T}}{T^2}\sum_{t=1}^{T} X_{t-1}^2\right)^{-1/2}$$

If (ε_t) is white noise, then $J = \lambda(0)$ and $\widehat{J_T} \approx \lambda_\varepsilon(0)$, respectively, which is consistent with the Dickey-Fuller test. If constants like in case 2 and 4 are considered, similar formulas can be created. These test statistics have the same asymptotic distribution as the Dickey-Fuller test statistics, which makes the use of the same statistics possible. The big advantage of the Philipp-Perron test is that the non-parametric autoregressive correction applies to general processes. In comparison to Dickey and Fuller, the Philipp and Perron Test is more powerful but has a bigger size distortion; this is why the null hypothesis too often gets rejected.[218]

4.2.2.3. KPSS-Test

Kwiatowski et al. developed a test that considers stationarity as the null hypothesis.[219]

If $(x_t),\ t = 1,2,\dots,T$[220] is the observed series that should be tested for stationarity. Kwiatowski et al. assume that this series can be decomposed into the sum of a deterministic trend, a random walk,[221] and a stationary error:

$$X_t = \delta t + r_t + \varepsilon_t,$$

where r_t, only in this subsection, represents a random walk $r_t = r_{t-1} + u_t$ and the u_t are iid $(0, \sigma_u^2)$. The initial value r_0 is fixed and represents the intercept.[222]

[218] Cf. Neusser 2011, p. 124.
[219] Cf. Horváth et al. 2014.
[220] Kwiatkowski et al. used the different notation of y_t here. To remain consistent with the other sections in this chapter, the y_t is changed to x_t.
[221] A random walk is a type of non-stationary process defined by $X_t = X_{t-1} + Z_t$, with $Z_t \sim WN(0, \sigma^2)$, where WN stands for white noise processes. This is further explained in subsection 4.3.1. Given any random variable X_0 and a sequence $(Z_{t.})$, the recursion is clearly defined for all X_t. For $t > 0$, $X_t = X_0 + Z_1 + \cdots + Z_t$ holds. The expected value of a random walk is $\mathbb{E}X_t = \mathbb{E}X_0$, but the variance of X_t varies with t, which is why a random walk is not stationary. Cf. Neusser 2011, p.16.
[222] Cf. Kwiatkowski et al. 1992, p. 162.

The stationarity null hypothesis is σ_u^2=0. With ε_t assumed to be stationary, X_t is trend-stationary under the null hypothesis. If $\delta t = 0$, the null hypothesis is that X_t is stationary around a level r_0 rather than around a trend. The one-sided LM statistic, which is the same as the locally best invariant (LBI) test statistic, is used for the hypothesis σ_u^2=0 and is defined below.[223] For σ_u^2=0, the strong assumption that u_t are normal distributed and ε_t are iid $N(0, \sigma_\varepsilon^2)$ must hold.[224]

This test statistic is computed as follows: let $d_t, t = 1,2, \dots, T$ be the residuals from the regression of X on an intercept and time trend and let $\widehat{\sigma_\varepsilon^2}$ be the estimate of the error variance from this regression (sum of squared residuals, divided by T). The partial sum of the process of the residuals is defined as

$$S_t = \sum_{i=1}^{t} d_i,$$

with $t = 1,2, \dots, T$. The LM and LBI statistic is then given by

$$LM = \sum_{t=1}^{T} S_t^2 / \widehat{\sigma_\varepsilon^2}.$$

For the testing level instead of trend stationarity, d_t is the residual from the regression of X on an intercept only ($d_t = X_t - \bar{X}$). The other computational steps remain unchanged. The test is an upper tail test.[225]

The statistic was derived based on the assumption that ε_t are iid $N(0, \sigma_\varepsilon^2)$. Kwiatowski et al. considered the asymptotic distribution of the LM statistic under weaker error assumptions. Assuming that ε_t satisfies the Philpps-Perron[226] regularity conditions for allowing general forms of temporal dependence, the authors therefore define the long-run variance as

$$\sigma^2 = \lim_{T \to \infty} T^{-1} E(S_T^2),$$

[223] For the LBI statistic, Kwiatowski et al. refer to Nabeya and Tanaka 1988. They use their results and translate them for the models they derived, see p. 161ff.
[224] Cf. Kwiatkowski et al. 1992, p. 162.
[225] Cf. Kwiatkowski et al. 1992, p. 163.
[226] Cf. Phillips and Perron 1988, p. 340.

which enters the asymptotic distribution of the test statistic. A consistent estimator of σ^2, here denoted as $s^2(l)$, can be constructed from the residuals d_t. This estimator (Newey-West estimator) is constructed as

$$s^2(l) = T^{-1}\sum_{t=1}^{T} d_t^2 + 2T^{-1}\sum_{s=l}^{l} w(s,l) \sum_{t=s+1}^{T} d_t d_{t-s},$$

with $w(s,l)$ acting as a weighting function which corresponds to the choice of spectral window.[227] For a positive $s^2(l)$, a Bartlett window $w(s,l) = 1 - \frac{s}{l+1}$ is used and, for consistency, the lag truncation parameter must satisfy $l \to \infty$ as $T \to \infty$. The rate $l = o(T^{\frac{1}{2}})$ will be satisfactory under the null and alternative hypothesis.[228] Then, when errors are not iid, the appropriate denominator of the test statistic becomes an estimate of σ^2 instead of σ_ε^2. Due to this, the numerator of the LM test statistics gets normalized with T^{-2}: $\eta = T^{-2}\sum S_t^2$. σ^2 is given through the consistent estimate, denoted here as $s^2(l)$, while η has an asymptotic distribution equal to σ^2 times a functional Brownian bridge. The division of $s^2(l)$ or another consistent estimate of σ^2 leads to an asymptotic distribution free of nuisance parameters.

This is demonstrated for the level- and trend-stationary case, as described in subsection 4.2.2.1. Considering $X_t = \delta t + r_t + \varepsilon_t$, with $\delta t = 0$, the residuals d_t come purely from the regression intercept, where $d_t = X - \bar{X}$. This means that S_t is the partial sum of the residuals. η_μ was defined above. The subscripted μ indicates that X is extracted by the mean but not by the trend of X. Due to this, the partial sums of the deviations from means of a process converge to a Brownian bridge, given that this sum satisfies the assumptions of Philipp and Perron. This implies the following:

$$\eta_\mu \to \sigma^2 \int_0^1 V(r)^2\, dr,$$

[227] Cf. Kwiatkowski et al. 1992, p. 164.
[228] Cf. Kwiatkowski et al. 1992, p. 164f., Newey and West 1987, p. 704f.

where $V(r)$ is a standard Brownian bridge with $V(r) = W(r) - rW(1)$ and $W(r)$ is a Wiener process.

The new test statics in than given by

$$\widehat{\eta_\mu} = \frac{\eta_\mu}{s^2(l)} = \frac{T^{-2}\sum_{t=1}^{T} S_t^2}{s^2(l)}.$$

Due to the consistency of $s^2(l)$, $\widehat{\eta_\mu} \to \int_0^1 V(r)^2\, dr$ follows. The trend stationary case is very similar. We again consider $X_t = \delta t + r_t + \varepsilon_t$ and d_t, representing the residuals from a regression of X_t on intercept and trend, and S_t is the partial sum of the residuals as defined as $S_t = \sum_{i=1}^{t} d_i$. As such, let η_τ be defined in the similar way as for trend stationarity $\eta_\tau \to \sigma^2 \int_0^1 V(r)^2\, dr$, where τ indicates that the mean and trend are extracted from X_t. From this, the partial sum of the process of the residuals from a regression of a process on intercept and trend satisfies the assumptions of Phillips and Perron and converges to a second level Brownian Bridge. This becomes

$$\eta_\tau \to \sigma^2 \int_0^1 V_2(r)^2\, dr,$$

where the second level Brownian Bridge $V_2(r)$ is given by $V_2(r) = W(r) + (2r - 3r^2)W(1) + (-6r + 6r^2)\int_0^1 W(s)ds$. The notation of the test statistics then stays the same:

$$\widehat{\eta_\tau} = \frac{\eta_t}{s^2(l)} = \frac{T^{-2}\sum_{t=1}^{T} S_t^2}{s^2(l)},$$

with the asymptotic distribution $\widehat{\eta_\tau} \to \int_0^1 V_2(r)^2\, dr$.

The critical values are provided in table 6:

Upper tail percentiles for the distribution $\widehat{\eta_\mu} \rightarrow \int_0^1 V(r)^2\, dr$				
Critical level:	0.10	0.05	0.025	0.01
Critical value:	0.347	0.463	0.574	0.739
Upper tail percentiles for the distribution $\widehat{\eta_\tau} \rightarrow \int_0^1 V_2(r)^2\, dr$				
Critical level:	0.10	0.05	0.025	0.01
Critical value:	0.119	0.146	0.176	0.216

Table 6: Upper tail critical values for η_μ and η_τ[229]

4.2.3. Conclusions Based on Empirical Findings

The results of the stationarity tests can be found in digital appendix F. For testing all three tests, we used the "Urca-Package" in R.[230] For the Augmented Dickey-Fuller Test we chose "drift" as our test type, as from visual inspection no trend was recognizable (case 2). We chose a lag of 100 to ensure that high autocorrelation had been considered. Comparing the test statistics with the theoretical statistics, we rejected the null-hypothesis for all of our 39 datasets on a 10%, 5%, and 1% significance level. This rejection indicated stationarity. For Philipp and Perron, we assumed a constant model, too. We tested both short and long versions of the lags used for the Newey-West estimator. The "Urca-Package" in R therefore uses a Bartlett window.[231] Again, we rejected the null hypothesis for both long and short lag versions for all of our 39 datasets on a 10%, 5%, and 1% significance level, indicating stationarity. For the KPSS test we chose type "mu", assuming a constant deterministic component and the long and short version of the Newey-West estimator again while short setting the number of lags to $\sqrt[4]{4 \times (\frac{n}{100})}$ and long to $\sqrt[4]{12 \times (\frac{n}{100})}$.[232] We accepted the null hypothesis for both long and short lag version on a 10%, 5%, and 1% for all of our 39 datasets, indicating stationarity. Since all three tests provide concordant results, we assume our data to be stationary.

4.3. Linear Stochastic Processes

4.3.1. White Noise Process

This chapter is devoted to autoregressive moving average models. This is necessary for our further GARCH analysis in section 4.4. since we want to prove whether or not the GARCH model needs a conditional mean model. We first provide explanations of white noise processes and autoregressive and moving average models. Following this, we outline the estimation and evaluation techniques of these models and present the conclusion based on our empirical results.

For the further explanations, it is necessary to provide knowledge about white noise processes. The basic idea of time-series analysis is to model complex processes through simple elements. The simplest one is represented by a white noise process. (Z_t) is a white noise process if (Z_t) is stationary,

$$\mathbb{E}Z_t = 0,$$

and

$$\gamma_Z(h) = \begin{cases} \sigma^2 & h = 0 \\ 0 & h \neq 0 \end{cases}.$$

A white noise process is denoted by $Z_t \sim WN(0, \sigma^2)$. This process is hence uncorrelated to time. Therefore, a prediction of future values is not possible due to the missing structure of the autocorrelation function. Hence, if (Z_t) is iid, this becomes $Z_t \sim IID(0, \sigma^2)$. If (Z_t) is, in addition, normally distributed, then $Z_t \sim IIN(0, \sigma^2)$. The white noise process is one of the easiest stochastic processes and is usable as a basis for the construction of more complex processes.[233]

[233] Cf. Neusser 2011, p. 14.

4.3.2. Autoregressive Models

Autoregressive models are based on the concept that the current value of the series (X_t) can be explained as a function of p past values, $x_{t-1}, x_{t-2}, \dots, x_{t-p}$, where p determines the number of steps into the past needed to forecast the current value. An autoregressive model of order p (AR(p)) is defined as

$$X_t = \phi_1 X_{t-1} + \phi_2 X_{t-2} + \cdots + \phi_p X_{t-p} + Z_t,$$

where X_t is stationary and $\phi_1, \phi_2, \dots, \phi_p$ are constant ($\phi_p \neq 0$). Unless otherwise stated, we assume that Z_t is a Gaussian white noise series with a mean of zero and a variance of σ_Z^2. Furthermore, we assume that the mean, μ, of X_t is zero. If it is not, we replace X by $X - \mu$, which leads us to

$$X_t - \mu = \phi_1 (X_{t-1} - \mu) + \phi_2 (X_{t-2} - \mu) + \cdots + \phi_p (X_{t-p} - \mu) + Z_t.$$ [234]

4.3.3. Moving Average Models

As an alternative to the AR(p) process, the moving average model of order q (MA(q)) assumes white noise Z_t on the right-hand side of the defining equation

$$X_t = \theta_0 Z_t + \theta_1 Z_{t-1} + \cdots + \theta_q Z_{t-q},$$

with $\theta_0 = 1$, $\theta_q \neq 0$, and $Z_t \sim WN(0, \sigma^2)$. For this process, $\mathbb{E}X_t = \mathbb{E}Z_t + \theta_1 \mathbb{E}Z_{t-1} + \cdots + \theta_q \mathbb{E}Z_{t-q} = 0$ is valid due to the white noise properties of Z_t.[235]

[234] Cf. Shumway and Stoffer 2011, p. 84ff.
[235] Cf. Neusser 2011, p. 23.

4.3.4. ARMA Models

ARMA models provide a more precise level of time-series modeling.

If (X_t), with $t \in \mathbb{T}$, is a stochastic process, then (X_t) is an autoregressive moving average process of the order (p, q). It is termed a ARMA(p,q) process if (X_t) is stationary and fulfills the following stochastic difference equation:

$$X_t - \phi_1 X_{t-1} - \cdots - \phi_p X_{t-p} = Z_t + \theta_1 Z_{t-1} + \cdots + \theta_q Z_{t-q},$$

with $Z_t \sim WN(0, \sigma^2)$ and $\phi_p \theta_q \neq 0$. (X_t) is considered a ARMA(p,q) process with mean μ if $(X_t - \mu)$ is an ARMA(p,q) process. Every stationary process can be approximated by an ARMA process of any desired level of accuracy. A c is often added often on the right side of the difference equation for ARMA(p,q) processes with mean μ:

$$X_t - \phi_1 X_{t-1} - \cdots - \phi_p X_{t-p} = c + Z_t + \theta_1 Z_{t-1} + \cdots + \theta_q Z_{t-q}.$$

The mean of X_t is then $\mu = \frac{c}{1-\phi_1-\cdots-\phi_p}$. Hence, the mean is only defined for $\phi_1 + \cdots + \phi_p \neq 1$.[236]

ARMA models require stationary data. For non-stationary data the concept of ARIMA is utilized (autoregressive integrated moving average model). These models are based on the assumption that non-stationary data become stationary after d-times of differentiation.[237] Since we only work with stationary data, we do not explain this concept further.

[236] Cf. Neusser 2011, p. 21f.
[237] Cf. Neusser 2011, p. 109.

4.3.5. Estimation of ARMA(p,q) Model

4.3.5.1. Choice of the orders p and q

To correctly choose the p and q of an ARMA model, it is recommended to have a good understanding of the time series' ACF and partial ACF (PACF). As explained in subsection 4.2.1., the ACF is a measure of association between -1 and 1 and measures the linear predictability of the series at time t, e.g., X_t using only the value X_s. Since ACF will be zero for MA(q)-models for lags greater than q,[238] the ACF provides information about the order of the dependence when the process is a moving average process. However, if the process is ARMA or AR, the ACF does not provide relevant information about the order of dependence on a standalone basis. Therefore, we introduce PACF as a function that behaves for AR processes in the same way an ACF does for MA processes. To motivate the idea, consider a causal AR(1) model $X_t = \phi X_{t-1} + Z_t$, which provides

$$\gamma_x(2) = cov(X_t, X_{t-2}) = cov(\phi X_{t-1} + Z_t, X_{t-2})$$
$$= cov\left(\phi^2 X_{t-2} + \phi Z_{t-1} + Z_{t,} X_{t-2}\right) = \phi^2 \gamma_x(0).$$

This result follows from causality[239] since X_{t-2} involves $(Z_{t-2}, Z_{t-3}, \dots)$, which are all uncorrelated with Z_t and Z_{t-1}. Hence, the correlation between X_t and X_{t-2} is not zero, as it would be for an MA(1) process, since X_t is dependent on X_{t-2} through X_{t-1}. Removing X_{t-1} breaks the chain of dependency and leads to the concept of PACF, where the correlation between X_s and X_t, with the linear effect of everything "in the middle", is removed. For the formal definition, let $\hat{X}_{t+h}$; for $h \geq 2$, denote the regression of X_{t+h} on $(x_{t+h-1}, x_{t+h-2}, \dots, x_{t+1})$, which can be written as

$$\hat{X}_{t+h} = \beta_1 X_{t+h-1} + \beta_2 X_{t+h-2} + \cdots + \beta_{h-1} X_{t+1.}$$

No intercept needs to be included here as the mean of X_t is zero. In addition, let $\hat{X}_t$ denote the regression of X_t on $(X_{t+1}, X_{t+2}, \dots, X_{t+h-1})$, then

[238] See Neusser 2011, p. 23 for further details about the behavior of autocovariance and autocorrelation functions of a MA(q) processes.
[239] The term causal is based on the assumption that only events in the past can have an effect on the future, but not vice versa. Cf. Neusser 2011, p. 27.

$$\hat{X}_t = \beta_1 X_{t+1} + \beta_2 X_{t+2} + \cdots + \beta_{h-1} X_{t+h-1}.$$

As we assume stationarity, the coefficients $\beta_1, \ldots \beta_{h-1}$ are the same for both regressions. PACF, for a stationary time series X_t, is defined as

$$\alpha_{11} = corr(X_{t+1}, X_t) = \rho(1)$$

and

$$\alpha_{hh} = corr\left(X_{t+h} - \hat{X}_{t+h}, X_t - \hat{X}_t\right), h \geq 2,$$

where both $(X_{t+h} - \hat{X}_{t+h})$ and $(X_t - \hat{X}_t)$ are uncorrelated with $(X_{t+1}, X_{t+2}, \ldots, X_{t+h-1})$. The PACF, α_{hh}, is the correlation between X_{t+h} and X_t, with the linear dependence of $(X_{t+1}, X_{t+2}, \ldots, X_{t+h-1})$ removed for both. If (X_t) is Gaussian, then $\alpha_{hh} = corr(X_{t+h}, X_t \mid X_{t+1}, \ldots, X_{t+h-1})$, where α_{hh} is the correlation coefficient between X_{t+h} and X_t is the bivariate distribution of (X_{t+h}, X_t), conditional on $(X_{t+1}, X_{t+2}, \ldots, X_{t+h-1})$.[240]

To see how PACF is used for the choice estimation of p and q, it is worthwhile looking at PACF for AR(p) and MA(q) processes. In the case of a PACF for an AR(p), the model process implies $X_{t+h} = \sum_{j=1}^{p} \phi_j X_{t+h-j} + Z_{t+h}$. When $h > p$, the regression of X_{t+h} on $(X_{t+1}, X_{t+2}, \ldots, X_{t+h-1})$ is $\hat{X}_{t+h} = \sum_{j=1}^{p} \phi_j X_{t+h-j}$.
When $h > p$,

$$\alpha_{hh} = corr\left(X_{t+h} - \hat{X}_{t+h}, X_t - \hat{X}_t\right) = corr\left(Z_{t+h}, X_t - \hat{X}_t\right) = 0,$$

since $X_t - \hat{X}_t$ depends only on $(Z_{t+h-1}, Z_{t+h-2}, \ldots)$ due to causality. If $h \leq p$, α_{pp} is not zero and $\phi_{11}, \ldots, \phi_{p-1,\ p-1}$ are not necessarily zero.

An invertible MA(q) process can be written as $X_t = -\sum_{j=1}^{\infty} \pi_j X_{t-j} + Z_t$. No finite representation exists and, hence, the PACF will never cut off, as in the case of an AR(p). For a MA(1) in general,

[240] Cf. Shumway and Stoffer 2011, p. 105f.; all parameters are adjusted to those used by Neusser, 2011.

$$\alpha_{hh} = -\frac{(-\theta)^h(1-\theta^2)}{1-\theta^{2(h+1)}}, h \geq 1.$$

These results can be summarized as follows:

	AR(p)	MA(q)	ARMA(p,q)
ACF	Tails off	Cuts off after lag q	Tails off
PACF	Cuts off after lag p	Tails off	Tails off

Table 7: Behavoir of ACF and PACF function for AR(p) and MA(q) processes[241]

4.3.5.2. Estimation of ARMA(p,q) Model

The standard technique for estimating an ARMA model is the maximum-likelihood method. Since the parameters of an AR(p) process are easy to estimate for the whole ARMA process, it is more difficult. This is because $Z_t, Z_{t-1}, \ldots, Z_{t-q}$ are not directly observable, which is why the maximum-likelihood method is used. We take a causal and invertible process

$$X_t - \phi_1 X_{t-1} - \cdots - \phi_p X_{t-p} = Z_t + \theta_1 Z_{t-1} + \cdots + \theta_q Z_{t-q}$$

as a basis, with $(Z_t) \sim IID\ (0, \sigma^2)$ and both $\Phi(z)$ and $\Theta(z)$ having no joint zero position. The parameters of the model are composed of the vector $\beta = (\phi_1, \ldots, \phi_p, \theta_1, \ldots, \theta_p)'$ and the scalar σ^2. Assuming the above-given values, the parameter space for β, $\mathcal{C}$ is provided by

$$\mathcal{C} = \left\{ \begin{array}{c} \beta \in \mathbb{R}^{p+q} : \Phi(z)\Theta(z) \neq 0 \text{ for } z \leq 1, \phi_p \theta_p \neq 0, \\ \Phi(z)\Theta(z) \text{ have no joint zero position} \end{array} \right\}$$

The maximum likelihood method tries to find solutions for β and σ^2, based on assumptions of the joint distribution $\boldsymbol{X}_T = (X_1, \ldots, X_T)'$, which maximize the probability for observing a given sample $\boldsymbol{x}_T = (x_1, \ldots, x_T)$. The density of the joint distribution is denoted as "likelihood function". If (X_t) is a Gaussian process with a mean of zero and

[241] Cf. Shumway and Stoffer 2011, p. 108.

autocovariance γ, then $\boldsymbol{X}_T = (X_1, \dots, X_T)'$ has a multivariate normal distribution with a mean of zero and the variance-covariance matrix Γ_T. The Gaussian likelihood function, given the observation $\boldsymbol{x}_T$, $L_T(\beta,\ \sigma^2|\boldsymbol{x}_T)$, is therefore

$$L_T(\beta,\ \sigma^2|\boldsymbol{x}_T) = (2\pi)^{-\frac{T}{2}} (\det \Gamma_T)^{-1/2} \exp\left(-\frac{1}{2}\boldsymbol{x}'_T \Gamma_T^{-1} \boldsymbol{x}_T\right)$$

$$= (2\pi\sigma^2)^{-\frac{T}{2}} (\det G_T)^{-1/2} \exp\left(-\frac{1}{2\sigma^2} x'_T G_T^{-1} \boldsymbol{x}_T\right),$$

with $G_T = \sigma^{-2}\Gamma_T$. The following step is to define β and σ^2 in that way that the value of the likelihood method is maximized. By differentiating the logarithm of $\boldsymbol{L}_T(\beta,\ \sigma^2|\boldsymbol{x}_T)$ with respect to σ^2 and setting this equal to zero, the optimal value for σ^2 can be calculated:

$$\frac{\partial L_T(\beta, \sigma^2|\boldsymbol{x}_T)}{\partial\ \sigma^2} = -\frac{T}{2}\frac{1}{\sigma^2} + \frac{\boldsymbol{X}'_T G_T^{-1} \boldsymbol{X}_T}{2\ \sigma^4} = 0.$$

Solving this equation, the result for σ^2 is $\sigma^2 = T^{-1}\boldsymbol{X}'_T G_T^{-1} \boldsymbol{X}_T$. Inserting the result in the logarithmical likelihood function leads to the concentrated logarithmized likelihood function

$$ln\ L_T(\beta|\boldsymbol{x}_T) = -\ln(2\pi) - \frac{T}{2}\ln(T^{-1}\boldsymbol{x}'_T G_T(\beta)^{-1} x_T) - \frac{1}{2}\ln\det G_T(\beta) - \frac{T}{2}.$$[242]

This function gets maximized over $\beta \in \mathcal{C}$, which is equivalent to the minimization of

$$l_T(\beta|\boldsymbol{x}_T) = \ln(T^{-1}\boldsymbol{x}'_T G_T(\beta)^{-1} x_T) + T^{-1}\ln\det G_T(\beta) \min_{\beta\in\mathcal{C}}.$$

The value of β that maximizes the above given function is the maximum likelihood estimator $\hat{\beta}_{ML}$. The maximum likelihood estimator for σ^2 is, hence, defined by

[242] As G_T only depends on β and not on σ^2, G_T is written here as $G_T(\beta)$ to highlight this fact (Neusser 2011, p.77. See also the different calculations for the autocovariance functions in section 2.4. of Neusser, where this fact becomes clear).

$$\hat{\sigma}^2_{ML} = T^{-1}\boldsymbol{x}'_T G_T(\hat{\beta}_{ML})^{-1}\boldsymbol{x}_T.$$

Since the numeric computation of $\det G_T(\beta)$ and $G_T(\beta)^{-1}$ is intricate, these terms are, in practice, replaced through corresponding algorithms, such as the innovation algorithm. That allows for numeric computation and a more suitable representation of the likelihood function

$$L_T(\beta, \sigma^2|\boldsymbol{x}_T) = (2\pi\sigma^2)^{-\frac{T}{2}}(m_0 m_1 \dots m_{T-1})^{-1/2}\exp\left(-\frac{1}{2\sigma^2}\sum_{t=1}^{T}\frac{(X_t - \mathbb{P}_{t-1}X_t)^2}{m_t - 1}\right),$$

where m_t is defined as $\frac{w_t}{\sigma^2}$, with w_t as the mean squared forecast error, and $\mathbb{P}_T X_{T+h}$ represents the linear forecast function $\mathbb{P}_T X_{T+h} = \alpha_0 + \alpha_1 X_T + \cdots + \alpha_T X_1 = \alpha_0 + \sum_{i=1}^{T}\alpha_i X_{T+1-i}$. Since $\mathbb{P}_{t-1}X_t$ and m_t do not depend on σ^2, partial differentiation of $ln\, L_T(\beta|\boldsymbol{x}_T)$ regarding the model parameter provides the maximum likelihood estimator. This fulfills

$$\hat{\sigma}^2{}_{ML} = \frac{1}{T}S(\hat{\beta}_{ML}),$$

where

$$S(\hat{\beta}_{ML}) = \sum_{t=1}^{T}\frac{(X_t - \mathbb{P}_{t-1}X_t)^2}{m_t - 1}.$$

Furthermore, $\hat{\beta}_{ML}$ is represented by the value of β, which minimizes the function

$$\ell_T(\beta|\boldsymbol{x}_T) = \ln\left(\frac{1}{T}S(\beta)\right) + \frac{1}{T}\sum_{t=1}^{T}\ln m_{t-1}$$

under the constraint $\beta \in \mathcal{C}$. The minimization problem must be solved numerically, meaning that starting values are often chosen from $\mathcal{C}$.[243] In R, the default setting for finding the right ARIMA parameters is the use of the conditional sum of squares method for finding starting values and then the use of maximum likelihood method.[244] The conditional sum of squares is represented by $S(\hat{\beta}_{ML})$.[245] Least square estimation $\hat{\beta}_{LS}$ of β

[243] Cf. Neusser 2011, p. 76ff., linear forecast function is represented on p. 53.
[244] Cf. Hyndman 2019, p. 11.
[245] Cf. Shumway and Stoffer 2011, p. 125ff.

is calculated by minimizing $S(\beta)$ instead of $\ell_T(\beta|\boldsymbol{x}_T)$, where $\beta \in \mathcal{C}$. Least square estimation $\hat{\sigma}^2$ becomes $\hat{\sigma}^2{}_{LS} = \frac{S(\hat{\beta}_{LS})}{T-p-q}$. Given $\beta \in \mathcal{C}$, the mean squared one-step forecast error w_t tends for T to infinity to σ^2 and, therefore, m_T tends to 1. As such, $\frac{1}{T}\sum_{t=1}^{T} \ln m_{t-1}$ is asymptotically negligible. Hence, for T towards infinity, the maximization of the maximum likelihood is equivalent to the minimization of the least square method, which is why both converge asymptotically to the same normal distribution.[246]

4.3.6. Ljung Box Test, ACF, and PACF

There are two approaches to investigate whether the financial return data require either an ARMA model or a conditional mean model in the GARCH context: Firstly, the ACF and PACF of the daily returns can be investigated to check for serial correlation, as described in subsection 4.3.5.1.[247] Since both ACF and PACF are based on a visual inspection, it is not completely clear whether the data are serial correlated or not. That is why we, secondly, make use of an empirical test. To prove whether the autocovariance is significant up to lags 5, 10, 15, or 20, the Box-Pierce statistic or the Ljung Box statistic may be used, respectively. The Box-Pierce statistic tests the null-hypothesis $\rho(1) = \rho(2) = \cdots = \rho(N) = 0, N = 1,2,$ ... The statistic is given by

$$Q = T\sum_{h=1}^{N} \hat{\rho}^2(h).$$

Under the null-hypothesis (X_t), a white noise process is asymptotically χ^2_N distributed. The Ljung Box statistic considers that the estimator of $\rho(h)$ correlations for large h values is based on lower values than for smaller h values. The test statistic is given by

$$Q' = T(T+2)\sum_{h=1}^{N} \frac{\hat{\rho}^2(h)}{T-h}$$

[246] Cf. Neusser 2011, p. 78f.
[247] Cf. Pfaff et al. 2016 and Zivot 2009.

and is asymptotically χ^2_N distributed too. The null-hypothesis is rejected for high values of Q and Q', respectively, and the critical values are determined by the χ^2_N distribution. The number of summands is commonly chosen to be between 5, 10, 15 and 20.[248] If the null hypothesis that all autocorrelations up to the tested lags are zero is rejected, this suggests that a conditional mean model is needed.[249]

4.3.7. Conclusions Based on Empirical Findings

Figure 7 displays the ACF and PACF for the in-sample Electricity returns of lags 0 to 20. The other figures are presented in digital appendix G.

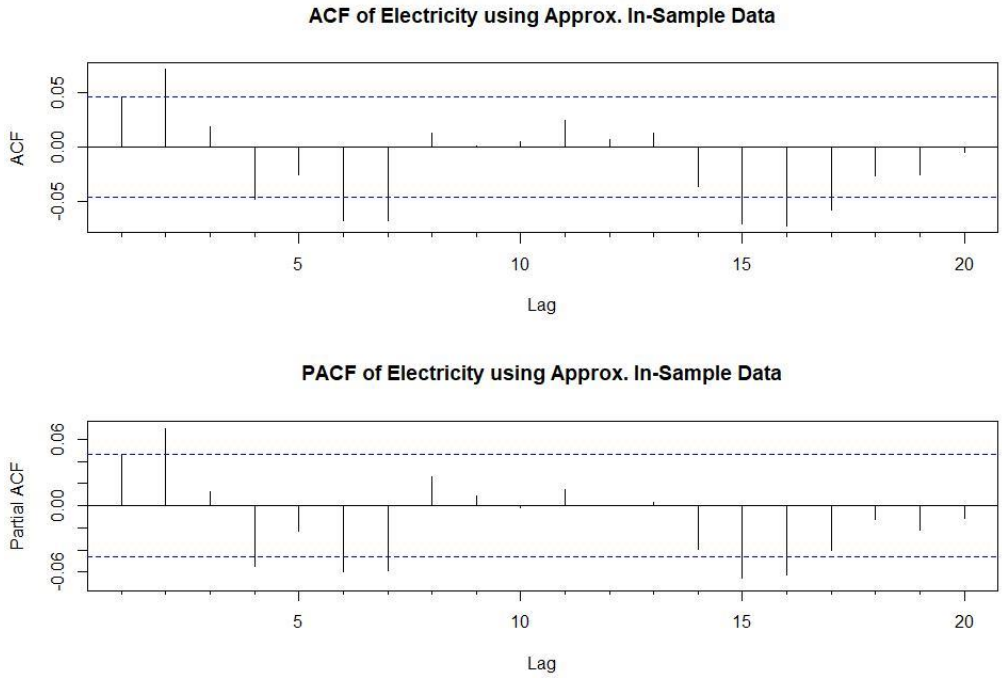

Figure 7: ACF and PACF of elecricity using approximated in-sample data

Based on the visual inspection of this example, it is clear that serial autocorrelation is occurring since lag 2, 4, 6 and 7 display significant results. To strengthen this result, and also for our other datasets, we investigated the Ljung Box test. If the null hypothesis that all autocorrelations up to lags tested at 5, 10, 15, and 20 is rejected, the use of a conditional mean model is suggested. This is, indeed, the case for the electricity returns. The results

[248] Cf. Neusser 2011, p. 42ff.
[249] Cf. Francq and Zakoian 2010, p. 108f.

of the other time series are presented in the table contained within digital appendix H. The same results occur for the following categories: cattle, aluminum, coffee, cotton, wheat, soybeans, forest and paper, electricity, fixed line communication, gas, water and multiutilities, industrial transportation, mobile telecommunication, oil and gas producers, oil, equipment services and distribution, airlines, real estate investment and services, REITS, beverages, STOXX Europe Total Market index, automobile and parts, and Bitcoin. The null hypothesis is accepted for all lags in the cases of cocoa, copper, lead, nickel, zinc, petroleum, software and computer services, REX, and DAXsubsector All Private Equity & Venture Capital. Mixed results are found for gold, silver, sugar, lean hogs, natural gas, alternative energy, technological equipment and hardware, chemicals and Litecoin.

For all time series where all lags were rejected and for those showing mixed results, we assume the need of a conditional mean model. To calculate that we used the auto.arima command in R, which includes all the calculation steps we presented before using maximum likelihood for parameter estimation.[250] For time series where all lags were accepted, we calculated a conditional mean model for the series with the auto.arima command too. We did this for three reasons: firstly, we wanted to see whether auto.arima confirms our results with a (0,0,0) model, which is identical to a white noise; secondly, we wanted to keep the heuristic procedure for all datasets homogenous; thirdly, our focus on the study is to find a comprehensive GARCH model, which is why there is no extensive focus on the conditional mean model. All of the auto.arima results are found in the table of digital appendix I. The white noise process was confirmed for lead, zinc, petroleum, and DAXsubsector All Private Equity & Venture Capital. For cocoa, copper, nickel, software and computer services, and REX, we decided to take the results of the auto.arima process to keep the procedure homogenous for all datasets. For the auto.arima process, we forced stationary results and did not allow a mean.[251]

[250] Cf. Hyndman 2019.

[251] At this point, we should mention that one may wonder whether a single ARMA model is sufficient to describe our data. In fact, we did exactly that at the beginning of our empirical work with a shorter dataset. We proved auto.arima, auto.arima with fourier terms an ETS Model, TBATS model, ARIMA with seasonal adjusted data via STL decomposition and a single STL decomposition (see Hyndman 2020 for more information). However, the results were not satisfactory. Therefore, we decided to extend the dataset to the existing one and to take the GARCH models into consideration. For model evaluation, we used Akaike Information Criterion, and the loss function RMSE, concepts further explained in subsection 4.4.5.

4.4. Volatility Models and Statistical Inference

4.4.1. Models

4.4.1.1. ARCH

Financial return time series are often subject to strong fluctuations. Periods of high volatility are followed by periods of low volatility. These amplitudes are, hence, positively autocorrelated since, with a high probability, high deflection in the amplitudes are followed by high deflections and low deflections are followed by low deflections in amplitude, a relationship that is in line with our findings in our section on stylized facts in subsection 3.2.2. Henceforth, the conditional variance (that is, the variance conditional on the past and is denoted as σ_t^2 throughout this section) of the one-step ahead forecast error is no longer constant (homoscedastic) but heteroscedastic. This phenomenon, which is mainly observed with high-frequency data (such as daily data) led to a large number of models that seek to capture these systemic changes in volatility.[252] Since ARMA models are traditional linear time-series models, they do not cover these stylized facts of financial return time series, which is in line with several findings in the literature and our own, outlined in footnote 251. An ARMA model for a series (Z_t) has the property that the conditional variance σ_t^2 of (Z_t) given $(Z_s, s < t)$ is independent of both t and $(Z_s, s < t)$.[253] To face this problem, Engle developed the ARCH (autoregressive conditional heteroskedasticity) model in 1982, which allows the conditional variance to depend on the past realizations of the series.[254] We present the ARCH model here to provide the fundamental basis for the GARCH models.

The main idea of ARCH is to incorporate the sequence (σ_t^2) into the model which leads to the following concept:

$$Z_t = \sigma_t e_t,$$

where $\{e_t\} \sim IID\ N(0,1)$ and (σ_t^2) is related to the past values of Z_t^2 via

[252] Cf. Neusser 2011, p. 139, Francq and Zakoian 2010, p. 19.
[253] Cf. Brockwell and Davis 2016, p. 196.
[254] Cf. Engle 1982.

$$\sigma_t^2 = \alpha_0 + \sum_{j=1}^{p} \alpha_j Z_{t-j}^2$$

for positive integer p, where $\alpha_0 > 0$ and $\alpha_j \geq 0, j = 1, \dots, p$.[255]

4.4.1.2. GARCH

The well-known GARCH (generalized ARCH) model introduced by Bollerslev[256] in 1986 as an extension of ARCH provides a more general relation and allows for a parsimonious parameterization:

$$\sigma_t^2 = \alpha_0 + \sum_{j=1}^{p} \alpha_j Z_{t-j}^2 + \sum_{j=1}^{q} \beta_j \sigma_{t-j}^2,$$

with $\alpha_0 > 0$ and $\alpha_j, \beta_j \geq 0, j = 1,2 \dots$. In financial data analysis, it is usually the case that better fits to data are obtained by relaxing the Gaussian assumption $Z_t = \sigma_t e_t, \{e_t\} \sim IID\ N(0,1)$ and supposing instead that the distribution has a heavier tailed zero-mean distribution (i.e., Student's t-distribution). To implement distributions like this, a GARCH(p,q) process can be defined as a stationary process (Z_t), with $Z_t = \sigma_t e_t, (e_t) \sim IID\ (0,1)$. In addition, it is usually assumed that either $(e_t) \sim N\ (0,1)$ or $\sqrt{\frac{v}{v-2}}\, e_t \sim t_v, v > 2$, where t_v denotes Student's t-distributions with v degrees of freedom. $\sqrt{\frac{v}{v-2}}$ is introduced to make the variance of e_t equal to 1.[257] As introduced, we analyze normal, Student's t- and general error distributions, which are explained in subsection 4.4.2 in more detail.

As mentioned above, one observed behavior of financial data is volatility clustering, which GARCH models are able to capture. This fact may be quantified in the persistence parameter. For the GARCH model this may be calculated as

[255] Cf. Brockwell and Davis 2016, p. 196.
[256] Cf. Bollerslev 1986.
[257] Cf. Brockwell and Davis 2016, p. 200f.

$$\hat{P} = \sum_{j=1}^{p} \alpha_j + \sum_{j=1}^{q} \beta_j.$$ [258]

For a stationary solution, $\hat{P}$ must be smaller than 1.[259]

4.4.1.3. IGARCH

The perception of the GARCH model leads us to the further extension of GARCH: the IGARCH model. When

$$\hat{P} = \sum_{j=1}^{p} \alpha_j + \sum_{j=1}^{q} \beta_j = 1,$$

the model is called an integrated GARCH(p,q) model or IGARCH(p,q) model.[260]

4.4.1.4. EGARCH

To consider different impacts of positive and negative values of e_t in the definition of the GARCH process and allow for different impacts on $\sigma_s^2, s > t$, Nelson (1991)[261] introduced the exponential GARCH model (EGARCH).[262] The exponential GARCH model is defined as

$$\ln(\sigma_t^2) = \alpha_0 + \sum_{j=1}^{p} \left(a_j e_{t-j} + \gamma_j \left(|e_{t-j}| - E|e_{t-j}| \right) \right) + \sum_{j=1}^{q} \beta_j ln(\sigma_{t-j}^2),$$

with a_j capturing the sign effect and γ_j in this subsection the size effect. The expected value of the absolute standardized innovation e_t is given by

[258] Cf. Ghalanos 2020, p. 7.
[259] Cf. Francq and Zakoian 2010, p. 37f.
[260] Cf. Ghalanos 2020, p. 7.
[261] Cf. Nelson 1991.
[262] Cf. Brockwell and Davis 2016, p. 205.

$$E|e_t| = \int_{-\infty}^{\infty} |e|\, f(e, 0,1, \dots) de$$

.

For model evaluating purposes, the persistence $\hat{P}$ of the model is necessary. For EGARCH models, the persistence is obtained through

$$\hat{P} = \sum_{j=1}^{q} \beta_j.$$ [263]

4.4.1.5. GJR-GARCH

The GJR GARCH model, developed by Glosten et al.[264], asymmetrically models positive and negative shocks on the conditional variance via the use of the indicator function I. The model is represented by

$$\sigma_t^2 = \alpha_0 + \sum_{\mathrm{j}=1}^{p} \left(a_j {Z^2}_{t-\mathrm{j}} + \gamma_j I_{t-\mathrm{j}} {Z^2}_{t-j}\right) + \sum_{j=1}^{q} \beta_j \sigma_{t-j}^2,$$

where γ_j in this subsection represents the "leverage" term. The indicator function I takes the value of 1 for $Z \leq 0$ and 0 otherwise. The persistence $\hat{P}$ of the model depends on the asymmetry of the conditional distribution, used because the indicator function is present. This is given by

$$\hat{P} = \sum_{j=1}^{p} a_j + \sum_{j=1}^{q} \beta_j + \sum_{j=1}^{p} \gamma_j\, \kappa,$$

where κ represents the expected value of the standardized residuals e_t below 0 (effectively the probability of being below zero), and

$$\kappa = E\left[I_{t-j} e_{t-j}^2\right] = \int_{-\infty}^{0} f(e, 0,1, \dots) de,$$

[263] Cf. Ghalanos 2020, p. 7; the formula was adapted according to Neusser 2011 and Brockwell and Davis 2016.
[264] Cf. Glosten et al. 1993.

where f represents the standardized conditional density with any additional skew and shape parameters $(\dots)$. In the case of symmetric distributions, the value of κ is simply equal to 0.5.[265]

4.4.1.6. CS-GARCH

This model was developed by Lee and Engle[266] in 1999. The component standard GARCH (csGARCH) model decomposes the conditional variance into a permanent and transitory component to investigate the long- and short-run movements of volatility affecting securities. If q_t represents the permanent component of the conditional variance, the component model is defined as the following:

$$\sigma_t^2 = q_t + \sum_{j=1}^{p} a_j\left({Z^2}_{t-j} - q_{t-j}\right) + \sum_{j=1}^{q} \beta_j\left(\sigma_{t-j}^2 - q_{t-j}\right)$$

$$q_t = a_0 + \rho q_{t-1} + \phi\left({Z^2}_{t-1} - \sigma_{t-j}^2\right),$$

where the intercept of the GARCH model is now time-varying, following first order autoregressive type dynamics. $\sigma_{t-j}^2 - q_{t-j}$ represents the transitory component of the conditional variance. The stationary conditions are that the sum of the (a, β) coefficients be less than 1 and that $\rho < 1$, effectively the persistence of the transitory and permanent components.[267]

[265] Cf. Ghalanos 2020, p. 7f.
[266] Cf. Lee and Engle 1999.
[267] Cf. Ghalanos 2020, p. 11f.

4.4.2. Conditional Distributions

4.4.2.1. Normal Distribution

As mentioned in subsection 4.4.1.2, we test the different GARCH models with different innovation distributions, which are introduced in the further subsections.

The normal distribution is completely described by its first two moments, mean and variance. A random variable x is said to be normal distributed with mean μ and variance σ^2, with its density given by

$$f(x) = \frac{\exp\left(\frac{-0.5\,(x-\mu)^2}{\sigma^2}\right)}{\sigma\sqrt{2\pi}}.$$

The residuals Z, standardized by σ, yield the normal density function given by

$$f\left(\frac{x-\mu}{\sigma}\right) = \frac{1}{\sigma}\,f(e) = \frac{1}{\sigma}\left(\frac{\exp\left(-0.5e^2\right)}{\sqrt{2\pi}}\right).$$ [268]

4.4.2.2. Student's t-Distribution

The Student's t-distribution is completely described by a shape parameter ν. For standardization we use its three-parameter representation:

$$f(x) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sqrt{\beta\nu\pi}\,\Gamma\left(\frac{\nu}{2}\right)}\left(1+\frac{(x-\alpha)^2}{\beta\nu}\right)^{-\left(\frac{\nu+1}{2}\right)},$$

[268] Cf. Ghalanos 2020, p. 18.

with α, β, and ν as location, scale and shape parameters, respectively. Γ is the Gamma function. The Student's t-distribution is a unimodal and symmetric distribution, where the location parameter α is the mean and mode of the distribution and the variance is

$$Var(x) = \frac{\beta\nu}{(\nu - 2)},$$

For the purposes of standardization, we require

$$Var(x) = \frac{\beta\nu}{(\nu - 2)} = 1,$$

which leads to

$$\frac{\nu - 2}{\nu} = \beta,$$

Substituting $\frac{\nu-2}{\nu}$ into the three-parameter representation, the standardized Student's t-distribution is given by

$$f\left(\frac{x-\mu}{\sigma}\right) = \frac{1}{\sigma}\, f(e) = \frac{1}{\sigma}\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sqrt{(\nu-2)\pi}\,\Gamma\left(\frac{\nu}{2}\right)}\left(1 + \frac{e^2}{(\nu-2)}\right)^{-\left(\frac{\nu+1}{2}\right)}.$$

R's standard implementation of Student's density "dt" is represented by

$$\frac{dt\left(\frac{Z_t}{\sigma\sqrt{(\nu-2)/\nu}}, \nu\right)}{\sigma\sqrt{(\nu-2)/\nu}}.$$

The Student's t-distribution has zero skewness and excess kurtosis equal to $6/(\nu - 4)$ for $\nu > 4$.[269]

[269] Cf. Ghalanos 2020, p. 18f.

4.4.2.3. General Error Distribution

The General Error Distribution is also a three-parameter distribution. This distribution belongs to the exponential family and has a conditional density that is given by

$$f(x) = \frac{\kappa \exp\left(-0.5\left|\frac{x-\alpha}{\beta}\right|^{\kappa}\right)}{2^{1+\kappa^{-1}}\beta\Gamma(\kappa^{-1})},$$

with α, β, and κ here representing location, scale, and shape parameters, respectively. The distribution is both symmetric and unimodal, which is why the location parameter also represents the mode, median and mean of the distribution. The variance and kurtosis are provided by

$$var(x) = \beta^2 2^{2/\kappa}\frac{\Gamma(3\kappa^{-1})}{\Gamma(\kappa^{-1})}$$

and

$$Kurtosis(x) = \frac{\Gamma(5\kappa^{-1})\Gamma(\kappa^{-1})}{\Gamma(3\kappa^{-1})\Gamma(3\kappa^{-1})}.$$

The density becomes increasingly flat as κ decreases, while the distribution tends towards the uniform as $\kappa \to \infty$. Standardization involves rescaling the density to have unit standard deviation:

$$var(x) = \beta^2 2^{2/\kappa}\frac{\Gamma(3\kappa^{-1})}{\Gamma(\kappa^{-1})} = 1,$$

which leads to

$$\beta = \sqrt{2^{-2/\kappa}\frac{\Gamma(\kappa^{-1})}{\Gamma(3\kappa^{-1})}}.$$

Substituting this into the scaled density of e:

$$f\left(\frac{x-\mu}{\sigma}\right) = \frac{1}{\sigma}\, f(e) = \frac{1}{\sigma} \frac{\kappa \exp\ -0.5 \left| \sqrt{2^{-2/\kappa} \frac{\Gamma(\kappa^{-1})}{\Gamma(3\kappa^{-1})}} e \right|^{\kappa}}{\sqrt{2^{-2/\kappa} \frac{\Gamma(\kappa^{-1})}{\Gamma(3\kappa^{-1})}} 2^{1+\kappa^{-1}} \Gamma(\kappa^{-1})}.$$ [270]

4.4.3. Estimation of GARCH by Quasi-Maximum-Likelihood

For the calculation of the volatility models, we use the maximum likelihood method. We assume the following mean equation:

$$X_t = c + \phi_1 X_{t-1} + \cdots + \phi_r X_{t-r} + Z_t.$$

For this equation, $Z_t = \sigma e_t$, with $e_t \sim IIDN(0,1)$ and the variance equation for $\sigma_t^2 = \alpha_0 + \sum_{j=1}^{p} \alpha_j Z_{t-j}^2 + \sum_{j=1}^{q} \beta_j \sigma_{t-j}^2$. The mean equation is, therefore, an AR(r) process. We further assume that the coefficients of the variance equation are positive, thereby allowing for $\sum_{j=1}^{p} \alpha_j + \sum_{j=1}^{q} \beta_j < 1$ and $\mathbb{E}{Z_t}^4 < \infty$. As $e_t \sim IIDN(0,1)$, the distribution of X_t conditional to $\mathfrak{X}_{t-1} = (X_{t-1}, X_{t-2}, \dots)$ is normally distributed with a mean $c + \phi_1 X_{t-1} + \cdots + \phi_r X_{t-r}$ and variance σ_t^2. As such, the density is denoted as

$$f(X_t|\mathfrak{X}_{t-1}) = \frac{1}{\sqrt{2\pi\sigma_t^2}} exp\left(-\frac{Z_t^2}{2\sigma_t^2}\right),$$

with $Z_t = X_t - \phi_1 X_{t-1} + \cdots + \phi_r X_{t-r}$ and σ_t^2 given by the variance equation. The density function $f(X_1, X_2, \dots, X_T)$ of a random sample $(X_1, X_2, \dots, X_T)$ can be factorized as follows:

$$f(X_1, X_2, \dots, X_T) = f(X_1, X_2, \dots, X_{s-1}) \prod_{t=s}^{T} f(X_t|\mathfrak{X}_{t-1}),$$

[270] Cf. Ghalanos 2020, p. 19.

where s represents an integral number bigger than p. The first $s-1$ observations do not need to be split further since, σ_t^2 within the ARCH(p) model, σ_t^2 is only defined for $s > p$. For ARCH, $s = p + 1$ is possible. In the GARCH model, σ_t^2 is given by an infinite weighted sum of $Z_{t-1}^2, Z_{t-2}^2, \ldots$. In finite samples, this infinite sum has to be approximated by a finite sum with s summands.

We summarize the parameter of the model to $\phi = (\phi_1, \ldots, \phi_r)', \alpha = (\alpha_0, \alpha_1, \ldots, \alpha_p)'$ and $\beta = (\beta_1, \ldots, \beta_q)'$. Given the realization $x = (x_1, x_2, \ldots, x_T)$, the likelihood-function conditional to $x, L(\phi, \alpha, \beta|x)$ is defined as

$$L(\phi, \alpha, \beta|x) = f(x_1, x_2, \ldots, x_{s-1}) \prod_{t=s}^{T} f(X_t|\mathfrak{X}_{t-1}),$$

whereas the random samples in $\mathfrak{X}_{t-1}$ are replaced by their realizations. The likelihood function can be interpreted as the probability of observing the actual sample. The Maximum-Likelihood now defines the parameters (ϕ, α, β) so that that likelihood function is maximized, thereby providing the Maximum Likelihood estimator. For practical reasons, the logarithm of the likelihood function is often used:

$$ln\, L(\phi, \alpha, \beta|x) = \sum_{t=s}^{T} \ln\, f(x_t|\mathfrak{X}_t) = -\frac{T}{2} \ln 2\pi - \frac{1}{2} \sum_{t=s}^{T} \ln \sigma_t^2 - \frac{1}{2} \sum_{t=s}^{T} \frac{z_t^2}{\sigma_t^2},$$

where $z_t = x_t - c - \phi_1 x_{t-1} - \cdots - \phi_r x_{t-r}$ as realizations of Z_t. The Maximum Likelihood estimator is then computed by maximizing the above equation. For e_t that are not normally distributed, the Maximum Likelihood estimator is then called the Quasi Maximum Likelihood estimator.[271]

[271] Cf. Neusser 2011, p. 149ff.

4.4.4. Test for Heteroscedasticity

To prove for volatility clustering, we take a further look at the squared returns and their autocorrelation function, since the procedure we used for ARMA models is also applicable on the GARCH context for squared returns.[272] Additionally, we calculate Engle's Lagrange-Multiplier test to prove for ARCH effects and, hence, the argumentation basis for a GARCH model. Both analyses are based on the null-hypothesis that no ARCH effects exists.

Engle's Lagrange-Multiplier test is based on a regression of squared residuals, based on the constant α_0 and $\hat{Z}_{t-1}^2$, $\hat{Z}_{t-2}^2$, …, $\hat{Z}_{t-p}^2$:

$$\hat{Z}_t^2 = \alpha_0 + \alpha_1 \hat{Z}_{t-1}^2 + \alpha_2 \hat{Z}_{t-2}^2 + \cdots + \alpha_q \hat{Z}_{t-p}^2 + \varepsilon_t,$$

with ε_t as regression error. The null hypothesis to be tested is $H_0: \alpha_1 = \alpha_2 = \cdots = \alpha_p = 0$ against $H_1: \alpha_j \neq 0$ for at least one j. The test statistic is given by TR^2, with T representing the sample size and R^2 computed from the regression using the estimated residuals; an F-test is also possible.[273] We use the p-value of the test statistics.

If there is evidence for autocorrelation, a model of autoregressive conditional heteroskedasticity is needed.[274]

[274] Cf. Zivot 2009.

4.4.5. Evaluation of GARCH Models

4.4.5.1. Akaike Information Criterion

As described in subsection 3.2.1, the third part of our model evaluation is carried out using the Akaike information criterion. Although we first consider the significance and persistence of the model parameters and the backtest results, we explain the concept here, as it is thematically directly related to the GARCH models. The idea of an information criterion is that, with increasing orders, the adjustment of the model, measured by the estimated variance of the residuals $\hat{\sigma}_{p,q}^2$, does not increase for the given data. To avoid overfitting, the information criterion is extended to a penalty term that depends on p and q. Most of the information criterions are given by the following equation:

$$\ln \hat{\sigma}_{p,q}^2 + (p+q)\frac{\mathrm{C(T)}}{T} \rightarrow \min_{p,q},$$

where $\ln \hat{\sigma}_{p,q}^2$ is the goodness of fit of the model and $(p+q)\frac{\mathrm{C(T)}}{T}$ denotes the penalty term. $\mathrm{C(T)}$ is a non-decreasing function representing the trade-off between the goodness of fit and the complexity of the model. There are several information criterions based on this formula, e.g., the Bayesian information criterion (BIC) and Hannan-Quinn information criterion (HQC).

For this thesis, we use the Akaike information criterion, denoted as

$$AIC\ (p,q) = \ln \hat{\sigma}_{p,q}^2 + (p+q)\frac{2}{T}.$$

Since the penalty term decreases with T, AIC allows models of higher orders with increasing T.[275] For the decision process we use AIC to evaluate which of the models works best.

[275] Cf. Neusser 2011, p. 82.

4.4.5.2. Loss-Functions and GARCH Diagnostics

For the sake of completeness, and as mentioned in subsection 3.2.1, we provide here a discussion of some key loss functions, namely MSE, MAE, R2LOG, QLIKE, PSE, and RMSE and the so-called "ugarchfit" diagnostics. For the out-of-sample evaluation, it is far from trivial to evaluate the forecasting performance of the different models. This is due to the unobservable latent nature of conditional volatility, which is why we need a proxy for the realized volatility. In their 1998 study, Andersen and Bollerslev made the point that use of daily squared returns as a proxy leads to very poor out-of-sample performance but significant in-sample fitting. This, they argued, could lead to skepticism regarding the forecasting availability of GARCH models. The authors showed that a better proxy for the latent volatility factor, using ex-post interdaily volatility measurements based on high-frequency intradaily data, produce strikingly accurate interdaily forecast.[276]

For empirical purposes, using the cumulative squared intra-day returns is difficult since high frequency data are often not available, as it is in our case too. Only High-Low intraday data were available for our dataset, which led us to use a simplified proxy, first introduced by Parkinson in 1980. The Parkinson estimator is denoted as

$$\hat{\sigma}_{P,t}^2 = \frac{(\ln(H_t) - \ln(L_t))^2}{4\ln(2)},$$

where H_t and L_t denote the highest and lowest daily prices, respectively.[277] We then calculated the following different loss functions motivated by the choice of Hansen and Lunde[278] with respect to RMSE:

[276] Cf. Andersen and Bollerslev 1998.
[277] Cf. Parkinson 1980, Kunitomo 1992.
[278] Cf. Hansen and Lunde 2005.

$$MSE = \frac{1}{n}\sum_{t=1}^{n}\left(\hat{\sigma}_{P,t}^{2} - {\sigma_t}^2\right)^2$$

$$QLIKE = \frac{1}{n}\sum_{t=1}^{n}\left(\ln {\sigma_t}^2 + \hat{\sigma}_{P,t}^{2}{\sigma_t}^{-2}\right)$$

$$MAE = \frac{1}{n}\sum_{t=1}^{n}\left|\hat{\sigma}_{P,t}^{2} - {\sigma_t}^2\right|$$

$$R^2LOG = \frac{1}{n}\sum_{t=1}^{n}\left(\ln \hat{\sigma}_{P,t}^{2}{\sigma_t}^{-2}\right)^2$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{t=1}^{n}\left(\hat{\sigma}_{P,t}^{2} - {\sigma_t}^2\right)^2}.$$

The lower the numbers are, the better the results. We proved this five times since it was not clear, which loss function is more appropriate.[279]

For further model evaluation, R provides the so-called "ugarchfit" diagnostics, which present the model parameters and a variety of tests for evaluating the quality of the models. First, the optimal parameters are presented with their standard errors and their robust versions, which are based on the method of White.[280] The p-values and parameter estimates used for this thesis follow the results of the robust standard error version. After these results, the information criteria Akaike, Bayes, Shibata and Hannan-Quinn are utilized. The weighted Ljung-Box test is a portmanteau test that evaluates the adequacy of the ARMA fit. The ARCH-LM statistics test is a weighted portmanteau test for evaluating the null hypothesis of the adequately fitted ARCH process; both are presented by Fisher and Gallagher.[281] The Engle and Ng's [282] Sign Bias Test presents the leverage effects in the standardized residuals, capturing possible misspecifications of the GARCH model by regressing the squared standardized residuals on lagged negative and positive shocks. The equation is as follows:

[279] Cf. Bollerslev et al. 1994.
[280] Cf. White 1982.
[281] Cf. Fisher and Gallagher 2012.
[282] Cf. Engle and Ng 1993.

$$\hat{z}_t^2 = c_0 + c_1 I_{\hat{y}_{t-1<0}} + c_2 I_{\hat{y}_{t-1<0}} \hat{y}_{t-1} + c_3 I_{\hat{\varepsilon}_{t-1\geq 0}} \hat{y}_{t-1} + u_{t,}$$

where I is the indicator function and $\hat{y}_t$ the estimated residuals from the GARCH process. The null hypotheses are $H_0: c_i = 0$ for $i = 1,2,3$ and that, jointly, $H_0: c_1 = c_2 = c_3 = 0$. The goodness of fit test calculates the chi-squared goodness of fit, which compares the empirical distribution of standardized residuals with the theoretical ones of the chosen density. The test is based on the results of Palm,[283] who adjusted the tests in the presence of non-iid observations by reclassifying the standard residuals, not according to their value but rather their magnitude. Therefore, the probability of observing a value smaller than the standardized residual is calculated and should be identical in its standard uniform distribution. The function takes the fitted object as the number of bins to classify the values as arguments. In the summary of the fit, a choice of (20, 30, 40, 50) bins is used. From the summary of the previous example, it is clear that the normal distribution does not adequately capture the empirical distribution based on this test.

Nyblom's parameter stability test[284] and the joint test are the last test of ugarchfit diagnostics. The Nymblom test is as good a measure of the parameter stability as the joint test.[285]

[283] Cf. Palm 1996.

[285] Cf. Ghalanos 2020, p. 27f.

4.5. Value at Risk

One of the most widely used risk terms is the value at risk. Although the value at risk is replaced by the expected shortfall in the newest Basel IV record,[286] it is still necessary for this thesis as we need it for McNeil's backtest.

The value at risk is the possible loss of a portfolio in a given time horizon. It is defined by a maximum loss which is not exceeded with a given probability. Consider a portfolio whose value at time t is a random variable denoted V_t. At a horizon h, the loss is defined as

$$L_{t,t+h} = -(V_{t+h} - V_t).$$

The distribution of $L_{t,t+h}$ is known as loss distribution. In general, V_t is specified as a function of k unobservable risk factors. The distribution of V_{t+h} conditional on the available information at time t is determined as the profit and loss (P&L) distribution. The determination of reserves depends on the portfolio. The available information at time t and the horizon h, and a level $\alpha \in (0,1)$ are both specified by regulators. The reserve is denoted as $RV_{t,h}(\alpha)$. Hence, the capital that has to be provided also includes the current portfolio value,

$$VaR_{t,h}(\alpha) = V_t + RV_{t,h}(\alpha),$$

and satisfies

$$P_t\left[V_{t+h} - V_t < -VaR_{t,h}(\alpha)\right] < \alpha$$

.

Here, P_t represents the probability conditional on the information available at time t, which means that, in probabilistic terms, $VaR_{t,h}(\alpha)$ is, thus, simply the $(1-\alpha)$-quantile of the conditional loss distributions

$$P_t\left[VaR_{t,h}(\alpha) < L_{t,t+h}\right] < \alpha$$

and

[286] Cf. Basel Committee on Banking Supervision 2019.

$$P_t\left[L_{t,t+h} \leq Var_{t,h}(\alpha)\right] \geq 1 - \alpha.$$

Here, P_t represents the probability conditional on the information available at time t, which means that, in probabilistic terms, $VaR_{t,h}(\alpha)$ is, thus, simply the $(1-\alpha)$-quantile of the conditional loss distributions

$$P_t\left[VaR_{t,h}(\alpha) < L_{t,t+h}\right] < \alpha$$

and

$$P_t\left[L_{t,t+h} \leq Var_{t,h}(\alpha)\right] \geq 1 - \alpha$$

.

This leads us to the following definition:

The $(1-\alpha)$-quantile of the conditional loss distribution is called the value at risk at confidence level α:

$$VaR_{t,h}(\alpha) := inf\{x \in \mathbb{R} | P_t\left[L_{t,t+h} \leq x\right] \geq 1 - \alpha\}$$

if the quantile is positive, by convention $Var_{t,h}(\alpha) = 0$ otherwise. This formula reduces the function of the value at risk to simply determining the quantile of the conditional loss distribution.[287]

4.6. Expected Shortfall

The expected shortfall is the risk measure required by the new Basel IV record[288] and is closely related to the value at risk. The advantage of the ES is that it avoids several conceptual difficulties; it is also more sensitive than the value at risk to the shape of the conditional loss distribution in the tail of the distribution. We assume the conditional

[287] Cf. Francq and Zakoian 2010, p. 327f.
[288] Cf. Basel Committee on Banking Supervision 2019.

distribution of $L_{t,t+h}$ to have a continuous and strictly increasing cfd. The expected shortfall at level α is the conditional expectation of the loss given that the loss exceeds the value at risk:

$$ES_{t,h}(\alpha) \coloneqq \mathbb{E}_t\left[L_{t,t+h} \middle| L_{t,t+h} > VaR_{t,h}(\alpha)\right].$$

For the calculation of the expected shortfall the following equation holds:

$$ES_{t,h}(\alpha) = \frac{1}{\alpha}\int_0^{\alpha} VaR_{t,h}(u)\, du.$$

Hence, ES can be interpreted for a given level α as the mean of the value at risk over all levels $u \leq \alpha$, which leads to $ES_{t,h}(\alpha) \geq VaR_{t,h}(\alpha)$. Due to the integral representation, $Es_{t,h}(\alpha)$ is a continuous function of α, regardless of the loss variable distribution.[289]

To estimate the loss distribution, we use the normal and student-t distributions. Although we have already seen that the normal distribution of our financial time series log return is not the best fit, we investigate this distribution as well since the QQ-plot only analysis is only based on ocular judgment.

The value at risk and expected shortfall for the Gaussian distribution are given by the following equations:

$$VaR_{\alpha} = \mu + \sigma\, \Phi^{-1}(\alpha)$$

and

$$ES_{\alpha} = \mu + \sigma \frac{\phi(\Phi^{-1}(\alpha))}{1-\alpha},$$

where Φ denotes the standard normal distribution function and ϕ its density.

The student-t distribution provides more probability mass in the tails, which is better for estimating our risk since log-returns of our time series are leptokurtic. Standard student-t-distributions have a mean of zero and a variance determined through its degree of freedom parameter. Value at risk and expected shortfall are calculated as

$$VaR_{\alpha} = \mu + \sigma t_{\nu}^{-1}(\alpha)$$

[289] Cf. Francq and Zakoian 2010, p. 332.

and

$$ES_\alpha = \mu + \sigma \frac{g_v(t_v^{-1}(\alpha))}{1-\alpha}\left(\frac{v + (t_v^{-1}(\alpha))^2}{v-1}\right),$$

respectively, where t_v denotes the distribution function and g_v the density of the student-t distribution.[290]

4.7. Backtesting Expected Shortfall

McNeil und Frey[291] developed an expected shortfall test based on exceedance residuals. Assuming that the dynamics of a stationary time series made up of daily observations are represented by $X_t = \mu_t + \sigma_t Z_t$, with innovations Z_t as a strict white noise process, the test is based on the discrepancy between $ES_t(\alpha)$ and X_{t+1}. The authors define the residuals as

$$RES_{t+1} = \frac{X_{t+1} + ES_t(\alpha)}{\sigma_{t+1}} = Z_{t+1} - E[Z|Z > z_\alpha].$$

The residuals are iid and have an expected value of zero. Standardizing the residuals is also possible by calculating the following:

$$RES^*_{t+1} = \frac{RES_{t+1}}{\sqrt{var(Z|Z > z_\alpha)}}$$

These residuals are iid and have mean of zero and a variance of one.

Suppose a backtest within the set T. The backtest is based on residuals for days where $x_{t+1} > x_\alpha^t$. We term these residuals "exceedance residuals". They are denoted by

$$\{res^*_{t+1} : t \in T, x_{t+1} > \hat{x}_\alpha^t\},$$

where

[290] Cf. Roccioletti 2016, p. 73f.
[291] Cf. McNeil and Frey 2000.

$$res^*_{t+1} = \frac{x_{t+1} - \widehat{ES}_t(\alpha)}{\hat{\sigma}_{t+1}\sqrt{\widehat{var}(Z|Z > z_\alpha)}}.$$

$\widehat{ES}_t$ is an estimate of the expected shortfall and $\widehat{var}(Z|Z > z_\alpha)$ is an estimate of the variance of the noise distribution truncated at z_α. Under the null hypothesis that the dynamics of $X_t = \mu_t + \sigma_t Z_t$ and the distributional assumption for the tail of the noise distribution are correct, the exceedance residuals should behave like an iid sample with a mean of zero and variance of one.[292]

We test this procedure by using the rugarch package's ESTest. The null hypothesis is that the excess expected shortfall (excess of the actual series when the value at risk is violated) is iid and has a mean of zero. The test is a one-sided t-test which checks the alternative that the excess shortfall has a mean greater than zero and, hence, that the expected shortfall is systematically underestimated. By using bootstrap to obtain the p-value, we should alleviate any bias with respect to the assumptions about the underlying distribution of the excess shortfall.[293]

[292] Cf. McNeil and Frey 2000.
[293] Cf. Ghalanos 2020, p. 44f.

4.8. Conclusion Based on Empirical Findings

Figure 8 displays our graphical findings for the squared returns of our electricity log return data.

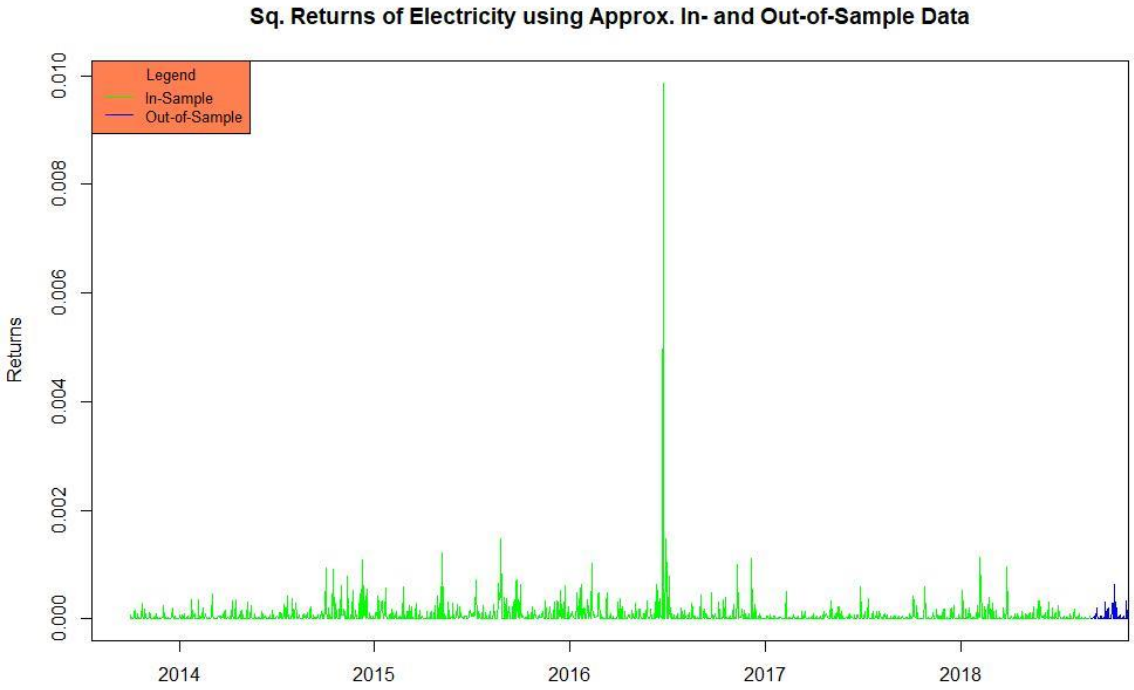

Figure 8: Squared returns of electricity using approximated in-and out-of-sample data

We see that the volatility clustering is evident, what is true for all our remaining results (see digital appendix J). The outlier is a result of Brexit as mentioned in subsection 3.1.3.

Figure 9 displays the ACF of the squared return of electricity log return squared data, which shows clearly significant autocorrelation.

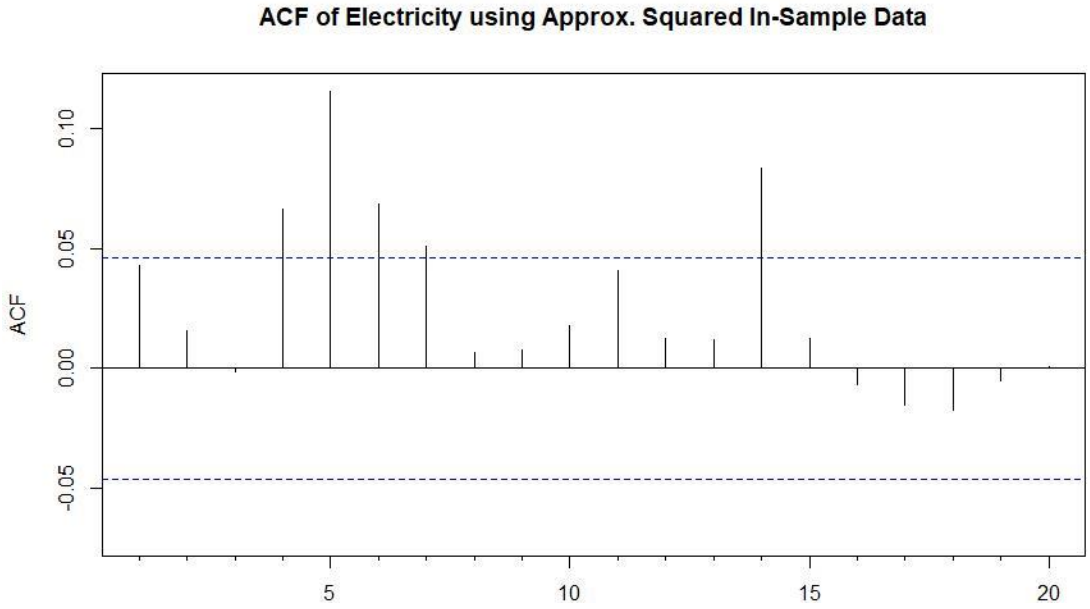

Figure 9: ACF of Electricity using Approximated Squared In-Sample data

These results hold for the rest of our data, too (see digital appendix K). With the exception of gold and zinc at lag 5, Engle's Lagrange Multiplier test rejects the null hypothesis that there is no autocorrelation for all time series at lags 5, 10, 15 and 20, confirming that the squared returns are serially correlated (see digital appendix L for the results). A GARCH model is, hence, needed for our log return data.

As described in subsection 4.3.7, our data require a conditional mean model. We extracted the auto.arima results of digital appendix I and included them in the ugarchspec function of the rugarch package commands to build to our GARCH models. We, therefore, tested the 60 different GARCH models on each of our 39 time series, providing 2340 results.

The 2340 models are listed in digital appendix M. For a better overview, we colored every dataset block differently and issued every model with a number. The numbers are visible in the first two columns. The model names are structured as follows: time series abbreviation as presented in table 1 + GARCH(p,q) model type + error distribution, e.g. DJACe11ged means Dow Jones All Cattle with an EGARCH(1,1) model and general error distribution, where "s" represents the standard GARCH model, "e" an EGARCH model, "g" a GJR-GARCH model, "i" an IGARCH model and "c" a CS-GARCH model.

The third column presents the models, the fourth, "Robust P-Values of Parameters", presents the significance of the model parameter. "NotS" means that at least one parameter of the model was not significant at a 5% level. All models marked with "NotS" were excluded for further analysis. Parameter and significance data can also be seen in detail in digital appendix M, next to the GARCH models tab. This procedure excluded Dow Jones both lead and gold time series as no significant models could be found; all other models had at least one significant model. The results of the loss functions using the Parkinson estimator are found in columns five to nine but were not taken into consideration for further model evaluation. "No Result" within the Parkinson estimator results means, that the model did not work and, hence, provided no result. The code for the loss functions is also included in digital appendix M.

We summarized the remaining models in the table of digital appendix N, which also represents a comprehensive overview of all results.[294] The second evaluation tool was persistence, which is listed in the fourth column of this table. Since none of the IGARCH models showed significant results, there is no model with a persistence equal to one. All other models fulfilled the persistence requirements.

For the results of the McNeil and Frey backtest, we first forecasted the 181 data points for the remaining models. For forecasting, we used the ugarchforecast command. In the forecast output, R provides both the series and sigma values. Results of the sigma and series values are presented in digital appendix O. Using these results, we estimated the value at risk and expected shortfall, as described in section 4.5. and 4.6., for the normal and Student's t-distributions at a 97.5% confidence level, in line with the Basel IV requirements.[295] For the Student's t-distribution we used 2.5 degrees of freedom. We derived this value from the model results of all GARCH models with Student's t-distribution, all providing degrees of freedom ranging between 2.100001 and 3.647092 (see digital appendix P for the degrees of freedom results).[296]

The results of the expected shortfall for normal and Student's t-distribution are presented in digital appendix Q. For the sake of completeness, we calculated the expected shortfalls of the actual out-of-sample data, too, as a comparison basis. R provides different methods

[294] The code for the GARCH diagnostics is the same as in appendix M as the data are extracted from the ugarchfit results. This is valid for columns 4, and 7–16. The code for column five and six is the code for the McNeil and Frey backtest.
[295] Cf. Basel Committee on Banking Supervision 2019, p. 89.
[296] The code for the degrees of freedom is the same as in appendix M as the data are extracted from the ugarchfit results.

for calculating the expected shortfall. We used the performance analytics method and the ES command. The command provides modified, Gaussian and historical methods. We used Gaussian to provide a comparison basis for the expected shortfall under normal distribution. To account for the Student's t-distribution, we added the modified method, which takes higher moments of non-normal distributions (skewness, kurtosis) into account using a Cornish-Fisher expansion. Moreover, for a complete comparison basis, we added the historical method. This method estimates a set of returns for the per-period ES using the negative value of the sample average of all returns below the quantile.[297] The results are displayed in digital appendix Q, too.

Using these results, we calculated the McNeil and Frey backtest. The results of the McNeil and Frey backtest are recorded in the columns "McNeil sst" and "McNeil nor" of the table in digital appendix N, columns 5 and 6. The test was deemed successful if the null hypothesis could not be rejected. For some of the results, it was not possible to calculate the McNeil backtest, either leading to "NA" results or "No valid ES model for ES distribution". The latter designation explains that the normal distribution is not adequate for modeling the expected shortfall, which is in line with Petersen et al.[298] For the former designation, the calculation technique of McNeil did not bring usable results; models with "NA" were, therefore, not taken into further consideration. Since the focus of our thesis is to prove whether a heuristic procedure can be used to find a comprehensive GARCH model, we conducted no further analysis of where the root of the "NA" values came from and excluded this data from our series. As the normal distribution did not provide usable results, we concentrated on the results of the McNeil backtest that used the Student's t-distribution. This procedure generally excluded two further time series: all cattle and copper. At least 179 models and 35 time series remained.

The seventh column of the table in digital appendix N provides the AIC for every model. We marked the lowest AIC for each time series, e.g., eight models remained for aluminum and, from these models, the EGARCH (1,2) model with ged distribution displayed the lowest AIC with -7.032597. For the sake of completeness, columns 8-16 of the table in digital appendix N summarize the GARCH diagnostics presented in subsection 4.4.5.2. The further result tabs of the table of digital appendix N present the results of GARCH diagnostics in detail. As can be seen, the specification tests indicated that none of the

[297] See Petersen et al. 2020 for further information.
[298] Cf. Petersen et al. 2020, p. 108.

models were perfect, but we accepted this imperfection since it was small relative to the fact that the model was able to forecast properly.

The table of digital appendix R summarizes the models with the lowest AIC per time series. Column two presents the model specification and column three the error distribution. We can see that EGARCH(1,2) and EGARCH(1,1) with ged distribution are the dominating models. From the 35 remaining series, eight work best with an EGARCH(1,1) with ged distribution, while 15 work best with an EGARCH(1,2) with ged distribution. Three further EGARCH(1,2) models work best with either normal or Student's t-distribution. The dominating model is, therefore, an EGARCH(1,2) with ged distribution model.

For the time series for which an EGARCH(1,2) ged model was not the best model, we investigated the table in digital appendix N again and checked whether the EGARCH(1,2) ged really did not work or if it was only the AIC for this model that was slightly worse. This was, indeed, the case for utility, wheat, and chemicals.

As we found that EGARCH(1,2) ged is the dominating model, we used it as the model for our portfolios. We included all of the time series listed in the table of digital appendix R. Columns five and six indicate the time series to which each subgroup belongs. As stated in subsection 3.1.1. and 3.2.1. for the STOXX Europe Total Market index, we regressed the subindices on the main STOXX index and used the residuals as new time series too. Hence, we investigated overweighting and regression-based portfolios. Results for the portfolios' expected shortfalls and backtest with the student t-distribution are located in digital appendix S.

All portfolios provide usable results and are predictable with an EGARCH(1,2) model with ged distribution. Exceptions to this include the following cases of overweighting: portfolio 9's "Energy" subgroup for 8.95%; portfolio 12's "Infrastructure Transportation" and "Infrastructure Utilities" subgroups for 1%; and portfolio 13's "Other" subgroup for both 5% and 1%. Results for the portfolios can be seen in digital appendix T.[299]

The comparison between the mean of the expected shortfall of all portfolios shows that most portfolios are risk-reduced for all cases. Risk reduction did not occur in the following subgroups: "Commodities Energy", portfolio 3, for case 8.95%; all

[299] The code for the results for the portfolios is the same as in appendix S as the data are extracted from the portfolio coding.

cryptocurrencies portfolios; and "Private Equity", portfolio 7, for cases 3% and 1%. The results for the cryptocurrencies portfolios are not totally in line in with the results of Symitsi and Chalvatzis[300] and Brière et al.[301], who showed evidence that Bitcoin can even lead to a significant reduction of overall portfolio risk. However, our results do agree with those of Pinudom et al.[302], who recognized an increasing risk when Bitcoin was added into a portfolio, and Stavroyiannis[303], who investigated that cryptocurrencies are subject to higher risk, a higher sufficient buffer, and risk capital.

The overweighted portfolios (portfolios 8-14) either did not work or show all risk increasing effects with respect to portfolio 8's "Emotionals" subgroup (for cases 5% and 1%), Portfolio 10's "Oil" subgroup (for cases 8.95% and 1%) and portfolio 11's "Infrastructure Telecommunications" subgroup (for cases 5% and 1%).

Our main finding is, hence, that an EGARCH(1,2) ged model can describe 18 of the single log return time series and all of our chosen portfolios with the exception of overweighting in the following cases: portfolios 9's "Energy" subgroup (for case 8.95%); portfolio 12's "Infrastructure Transportation" and "Infrastructure Utilities" subgroups (for case 1%); and portfolio 13's "Other" subgroup (for case 1%). Mostofwi et al.[304] understood alternatives investments to be a heterogeneous group of investment opportunities that differ from traditional investments in terms of their risk and return and certain other characteristics. Our results do not confirm this, at least not totally, since the EGARCH(1,2) ged model describes both alternative investments and traditional investments. The results obtained from the EGARCH ged distribution model are in line with Ekong and Onye,[305] who found that an EGARCH(1,1) model with ged performance works best. In line with Hansen und Lunde[306], we tested more combinations than p,q=(1,1), which was the correct approach since the p,q=(1,2) outperformed the p,q=(1,1) solution. Furthermore, obtaining these results was made possible by using a heuristic procedure. We could also conclude that adding alternative investments to a portfolio of traditional investments reduces risk in many cases. The following table summarizes our results:

Table 8: Summarized results of the data analysis

5. Conclusion

This section provides a short summary of the results and the main conclusions.

The thesis deals with alternative investments and their qualitative and statistical properties. We examined four main themes. First, we investigated whether it is possible to describe a dataset comprising 37 univariate alternative and two univariate traditional investment return time series using one comprehensive GARCH model. Secondly, we investigated whether finding this model is possible by using a heuristic procedure. Thirdly, we examined whether the alternative asset classes have a risk-reducing effect on a portfolio with traditional investments. Finally, we proved whether the comprehensive model was also applicable to the constructed portfolios.

The analysis was done from the perspective of a European bank. This allowed us to conduct for the regulatory requirements of Basel IV. Hence, the focus of the thesis was on risk rather than return. To ensure a homogenous dataset, European data were used when it was possible.

To address the four research questions, we first provided definitions and conducted a literature review of alternative investments to provide a unique discussion basis. The analysis was based on 39 financial time series consisting of the following asset classes: commodity futures, cryptocurrencies, private equity, REITS, bonds, and different European stocks indices, where bonds and the STOXX Europe Total Market index represented traditional investments. With the exception of Dow Jones Commodity, we concentrated on European data valued in euros. Our data consisted of daily values over the period from October 2013 to February 2019. For backtesting purposes, we split our sample into in-sample and out-of-sample groups.

Our investigative approach was based on stylized facts, in that financial time series have common statistical properties. As our alternative investment dataset only consisted of financial time series data and further studies confirmed that these stylized facts are also valid for cryptocurrencies, we assumed that a comprehensive GARCH model working for all of the selected univariate time series can be found. As a result, we analyzed the 39 univariate time series and assessed whether one of 60 different GARCH models works as an overall model for all univariate time series. This led to 2340 results. The choice of GARCH model and error distribution was motivated by findings in the literature. The

model assessment was carried out in three steps: first, evaluating the significance and persistence of model parameter; second, evaluating the results of McNeil and Frey backtest; and lastly, evaluating the AIC. We then found that an EGARCH(1,2) ged model is the dominating model for the univariate time series.

To apply the univariate EGARCH(1,2) ged model on portfolios, we created portfolios as new univariate time series by adding and weighting the different asset classes into subgroups. We clustered similar financial time series into asset-class groups. The first subgroup represented our traditional and reference portfolio with bonds and equities. The ratio between bonds and equities was derived from data published by the Deutsche Bundesbank. We then created 13 subgroups out of the remaining 37 alternative investment classes time series. The time series within the 13 subgroups were equally weighted. Knowing well that eight subgroups contain sub-indices of the STOXX Europe Total Market index, we regressed the sub-indices on this index and treated the linear regression residuals as an adjusted time series to account for overweighting. We then repeated all calculation steps on the portfolios and, using regression, compared the 13x4 portfolios and 8x4 portfolios to our reference portfolio in terms of expected shortfall. We, therefore, built the average of all forecasted expected shortfalls on the out-of-sample horizon and compared these to subgroup 1's reference portfolio.

Our main finding was that an EGARCH(1,2) with a general error distribution model can describe 18 of the 39 single log return time series and nearly all of the portfolios. Table 8 in section 4.8. shows which GARCH model describes each time series best and how each of the alternative investment subgroups behaves in a portfolio. Hence, the statistical properties of the alternative and traditional investments are comparable in terms of volatility and volatility modeling. Furthermore, finding these results was possible by using a heuristic procedure. We also showed that alternative investments, including cryptocurrencies, do, in most cases, yield to reduce risk of portfolios with traditional investments.

Due to the similar statistical properties of alternative and traditional asset classes and the dominant EGARCH(1,2) ged model, European banks can significantly reduce the complexity of modeling their alternative and traditional asset time series. This is particularly interesting for their internal risk management and bank control processes as well as for their value-based management. The risk reduction in portfolios with traditional investments also suggests a reduction in capital requirements forced by Basel IV. The

concrete calculation of this reduction was not the subject of this thesis. Thus, this statement remains only of general but not empirically proven importance and remains a starting point for further studies. Based on the dataset used here and the assumptions and simplifications made regarding the dataset and calculations, we recommend European banks to invest in alternative asset classes. In order to provide exact information about the investment volume and weighting which leads to the greatest risk reduction and return maximization a detailed portfolio optimization analysis would be necessary as well as the use of different datasets and time horizons to also provide the possibility for robustness checks. Also, an analysis of multivariate GARCH models or correlation effects between the single time series would therefore be necessary and hence represents a starting point for further research. Additionally, the discussion on the alternative asset classes could be extended in further studies. First, complex, non-traditional strategies could be analyzed as well as hedge fund data. Furthermore, a discussion on whether cryptocurrencies should be evaluated as a separate asset class could also be done. Finally, the collection of real alternative investment data instead of proxies would be another point for further analysis.
